THE AMERICAN JOURNAL OF PSYCHIATRY

11

In this issue

John G. Gunderson and Margaret T. Singer on Defining Borderline Patients

OFFICIAL JOURNAL OF THE AMERICAN PSYCHIATRIC ASSOCIATION

UNIVERSITY COLLEGE OF MEDICINE LIBRARY

You know what to expect:

DEPENDABILITY

For effective management of psychotic symptoms

- unsurpassed clinical experience
- widely researched and documented
- 18 dosage forms and strengths for maximum flexibility

fore prescribing, see complete prescribing formation in SK&F literature or *PDR*. The ollowing is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol.

©1967, 1968, 1969 SmithKline Corporation

May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100 and Single Unit Packages of 100. Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50 and Single Unit Packages of 100. Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate, 30 mg./ml. and 100 mg./ml.

Smith Kline & French Laboratories

THORAZINE®

brand of **CHLORPROMAZINE** Tablets: 50 mg. of the HCl

That's no surprise.

P 24,345

complete your psychiatric setting.

Include a McGraw-Hill text...

BEHAVIORAL THERAPY, Second Edition
Halmuth H. Schaefer, The University of Auckland, and **Patrick L. Martin,** Pacific State Hospital, Pomona, California.
1975, 352 pages (tent.), $6.95 (tent.)

Including five new chapters on mental retardation and information on follow-up care for the patient outside the hospital, the Second Edition of this informative text prepares mental health professionals for the application of behavioral techniques to the field of public mental health care. Extensive material has been added on recently developed techniques in quasi-behavioral methods, alcoholism, and preventive community health care.

PSYCHIATRIC TREATMENT: CRISIS, CLINIC, AND CONSULTATION. Edited by **C. Peter Rosenbaum** and **John E. Beebe,** both of the Stanford University School of Medicine.
1975, 640 pages (tent.), $15.00 (tent.)

Practically oriented and comprehensive, this text provides mental health professionals with an understanding of the kinds of issues they face working with patients who are in crisis, who need outpatient therapy, or about whom they are consulting. Focusing on the therapist's experience in the clinical situation, the book provides both a theoretical understanding of problem and treatment and a series of practical suggestions on how the therapist can proceed in various clinical situations.

THE HUMAN NERVOUS SYSTEM: BASIC PRINCIPLES OF NEUROBIOLOGY, SECOND EDITION. **Charles R. Noback** and **Robert J. Demarest,** both of the College of Physicians and Surgeons, Columbia University. 1975, 512 pages (tent.), $14.95 (tent.)

Extensively revised, the Second Edition of this popular text has increased its coverage throughout of topics in neurobiology, neuroanatomy and neurophysiology. Over half the illustrations are new, and there is new information dealing with advances in areas such as neural pathways and feedback systems, the ultrastructure of the retina, and in the concepts of contrast inhibition. The chapter on "Development and Growth of the Nervous System" has also been updated.

THE UNDERSTANDING OF THE BRAIN
John C. Eccles, Ph.D., State University of New York at Buffalo.
1973, 224 pages, $5.95 hard; $3.95 soft.

This is a Nobel Laureate's stimulating, far-reaching introduction to neurophysiology. The text ranges from the simplest phenomena of inverterbrate nervous systems to the role of the human brain in cognition, creativity, and volition. Including both philosophical and psychological concepts, Dr. Eccles examines the nature of the conscious self, the role of language, and the problem of life's meaning.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

1700 Eighteenth Street, N.W., Washington, D.C. 20009

OFFICERS 1974–1975

President: JOHN P. SPIEGEL
President-Elect: JUDD MARMOR
Vice-President: JUNE J. CHRISTMAS

Five Separate Campuses

Five **separate campuses** providing individually prescribed programs of care, education, treatment and training for children, adolescents and adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.

Advantage: the availability of **a large trained and experienced staff,** exchanging ideas and insights in a comprehensive program of supportive environment and individualized treatment.

Advantage: **geographically separated** to provide the proper residential milieu . . yet near enough to benefit from the combined training and experience of a wide range of staff members.

THE OAKS— intensive residential psychiatric treatment for emotionally disturbed children and adolescents to 16 years of age. Coeducational, Austin.

Brown Hall–90 ACRES-Residential psychiatric treatment and training for older children and adolescents with learning disabilities, neurological impairment, mental retardation and varying degrees of emotional disturbance. Brown Hall, young men; 90 Acres, young women. San Marcos.

Hillview and The Ranch—longer term care and treatment for those who must continue to live in a protected environment; prevocational training, Hillview, coeducational, San Marcos. Ranch, males only, Austin.

THE BROWN SCHOOLS

The February 1975 issue of

The American Journal of Psychiatry

will feature

- Philip D. Walls, Lichun Han Walls, and Donald G. Langsley on Psychiatric Training and Practice in the People's Republic of China

Tofranil-PM®
imipramine pamoate

Capsules* of 150, 125, 100 and 75 mg.

One capsule lasts from bedtime to bedtime.

For single-dose therapy in depression when the dosage is established.

- simple enough dosage regimen to help avoid missed doses.
- while daily dosage ranges from 75 to 300 mg., the 150-mg. capsule may be the most effective daily dose for many patients.
- becomes part of the regular bedtime routine—making it easier to establish a more reliable pattern of self-medication.
- safety/efficacy ratio equivalent to divided daily doses.
- provides a full range of single daily dosage strengths to facilitate increasing or gradually decreasing medication.
- saves time and cost of dosage administration in the hospital.

Please read the prescribing information for details of usage, precautions, warnings, contraindications, adverse experiences, and dosage recommendations. A summary of this information appears on the following page.

*Each capsule contains imipramine pamoate equivalent to 150, 125, 100 or 75 mg. of imipramine hydrochloride.

Tofranil-PM® Geigy
imipramine pamoate

One capsule lasts from bedtime to bedtime.

Tofranil-PM®
brand of imipramine pamoate
Tofranil®
brand of imipramine hydrochloride USP

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil, brand of imipramine hydrochloride, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;

—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;

—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;

—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;

—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Usage in Children: Pending evaluation of results from clinical trials in children, Tofranil, brand of imipramine hydrochloride, is not recommended for treatment of depression in patients under twelve years of age.

Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as operating an automobile or machinery, the patient should be cautioned accordingly.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil, brand of imipramine hydrochloride, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil, brand of imipramine hydrochloride, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine hydrochloride should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: Lower dosages are recommended for elderly patients and adolescents. Lower dosages are also recommended for outpatients as compared to hospitalized patients who will be under close supervision. Dosage should be initiated with Tofranil, brand of imipramine hydrochloride, at a low level and increased gradually, noting carefully the clinical response and any evidence of intolerance. Following remission, maintenance medication may be required for a longer period of time, at the lowest dose that will maintain remission.

Once-a-day maintenance dosage can be provided with Tofranil-PM, brand of imipramine pamoate, capsules if this dosage has been established as explained above. This dose may be given at bedtime. For the occasional patient who manifests stimulation and insomnia with this dosage regimen, the capsules may be given in the morning.

Parenteral administration should be used only for starting therapy in patients unable or unwilling to use oral medication. The oral form should supplant the injectable as soon as possible.

How Supplied: Tofranil, brand of imipramine hydrochloride: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg.; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.

Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.) (B) 98-146-850-P (2/74)

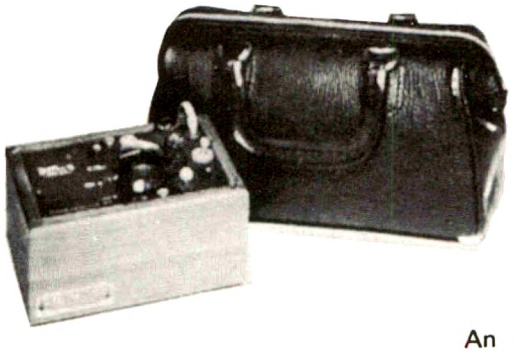
TO 19604

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models– **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS–THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives–patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes –a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

For more detailed information, and bibliography of over 200 references, write to:

ELAVIL®
(AMITRIPTYLINE HCl|MSD)
useful in many therapeutic settings

In the psychiatrist's office. Whatever other therapeutic facilities have been developed, the psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations.

In the general hospital. The general hospital today usually provides a psychiatric unit where depressed patients may be treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

In the outpatient clinic. With follow-up treatment often necessary for three months or longer, ELAVIL is highly effective in maintaining relief, especially in patients who responded well to higher doses while hospitalized. As a result, these patients may continue to function in their daily activities.

In the mental hospital. Here where severely depressed patients present challenges for psychiatrist and staff alike, the usefulness of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

In the community mental health center. A remarkable innovation in the field of modern psychiatry, this center offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

Should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

In many therapeutic settings—one proven antidepressant

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

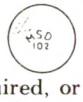
MSD
MERCK SHARP & DOHME

addendum



ELAVIL®
(AMITRIPTYLINE HCl | MSD)
dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for initial therapy in adult outpatients. Starting dosage is usually 75 mg daily in divided doses or 50 to 100 mg once a day at bedtime. If necessary, this dosage may be increased gradually to a total of 150 mg a day. When doses are divided, dosage increases are made preferably in the late afternoon or at bedtime. A sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be advantageous whenever higher dosages are required, or when the single daily dose is given at bedtime. The 50-mg tablet may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of tricyclic antidepressant poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

FELLOWSHIP PAPERWEIGHT

Here's a way to indicate everyday you're a Fellow of the American Psychiatric Association. A handsome polished white marble paperweight on which a facsimile of the Fellowship Medal appears, with the word "Fellow" on a polished chrome background appearing below, is available for your desk. Immediate shipment, while the supply lasts, (after which there may be a six weeks delay for reorder), at a cost of $4.00 which includes processing your order, packaging, and postage.

MEMBERSHIP DESK PEN

For Members, order a handsome custom-made Park Pen desk set. It is a two-inch cube of white Italian marble with a customized replica of the APA seal, one and a half inch in diameter, with a Parker desk pen, handsomely gift boxed, available in this initial offering at $9 each. Immediate shipment is possible while the supply lasts. Reorder subject to six weeks delay.

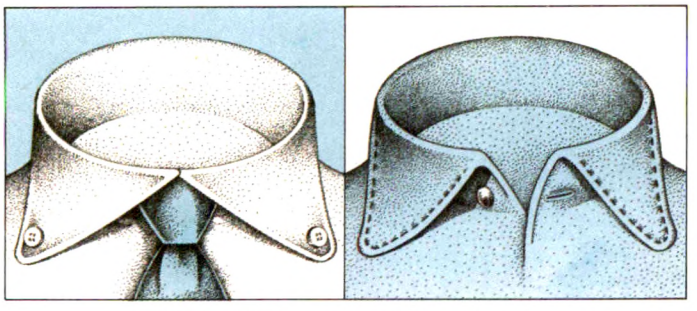
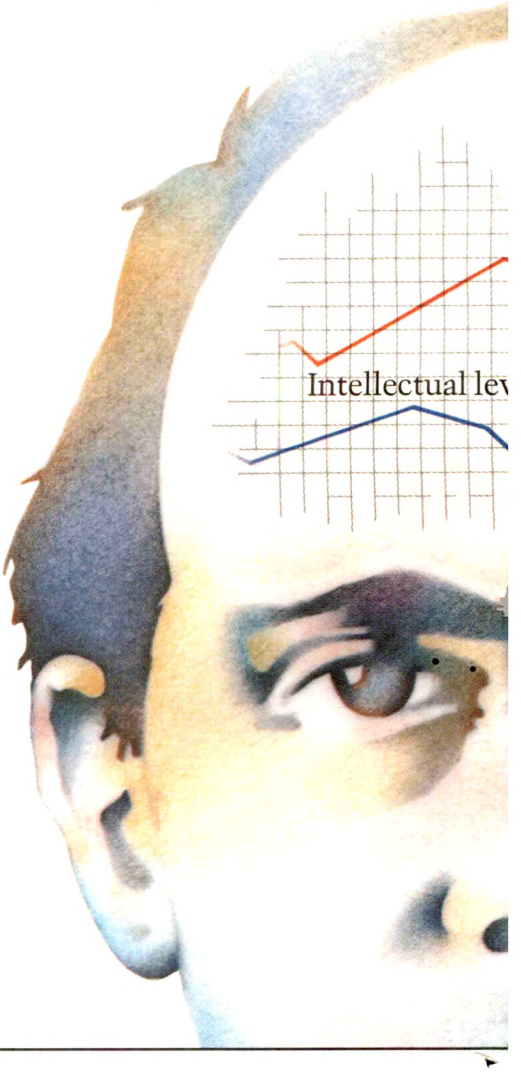
How individual patient variables influence

It is now well established that certain nondrug factors can affect response to antianxiety medication. Thus, even with agents of proven efficacy, such as Librium (chlordiazepoxide HCl), different patients may exhibit varying degrees of symptomatic relief from excessive anxiety and tension.



Apart from the effect of the physician's personality and prescribing attitudes on patient response,[1] there are certain significant patient variables, *e.g.*, personality type, severity and duration of anxiety, socioeconomic status, attitude toward medication and insight into the nature of the condition under treatment.[2-4] Thus, some clinical experience suggests that physically active extroverts, for whom abatement of anxiety may decrease the will to achieve or take action, may respond negatively – resulting in exacerbation of anxiety.[2] On the other hand, more passively anxious individuals with intellectual and esthetic inclinations have been shown to benefit from antianxiety medications.

When medication is indicated in the latter group, many psychiatrists place a high value on the benzodiazepines – of which Librium (chlordiazepoxide HCl) was the first in clinical use – for their antianxiety effectiveness, broad usefulness and wide margin of safety.[2,3]



1. Rickels K, Lipman RS, Park LC, Covi L, Uhlenhuth EH, Mock JE: *Psychopharmacologia 20*:128-152, 1971
2. Hollister LE: *Ann Intern Med* 79:88-98, July 1973
3. Greenblatt DJ, Shader RI: *Ibid.*, 77: 91-100, July 1972
4. Rickels K, Downing RW, Howard K: *Clin Pharmacol Ther 12*:263-273, Mar-Apr 1971

Attitude to medication

Socioeconomic status

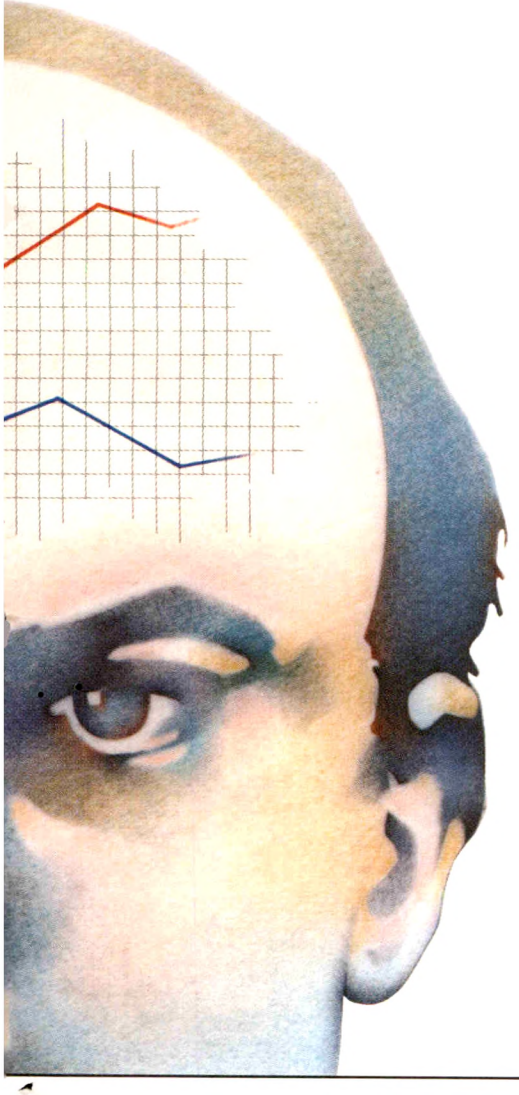
the effectiveness of antianxiety therapy

Demonstrated predictors of favorable response to Librium (chlordiazepoxide HCl)

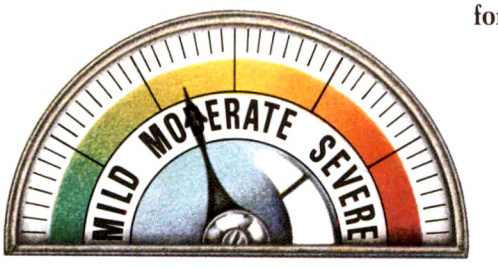
In a double-blind, controlled study[4] of psychoneurotic patients with moderately severe anxiety, 111 patients were treated with Librium in a daily dosage of 30 to 40 mg, and 201 patients received a placebo. Outcome criteria included a global improvement measure after 2 and 4 weeks and the 4-week change score of a 10-item physician questionnaire.

Statistical analysis revealed that the greatest drug-placebo difference in relieving anxiety occurred among patients who were more severely ill, those in a higher socioeconomic class and those whose illness had persisted for at least six months. The more educated patient with high verbal ability, greater insight and an accepting attitude toward combined psychotherapy and drug therapy responded *significantly better* to Librium than to the placebo. On the other hand, patients of lower socioeconomic status, with less insight and greater readiness to accept medication alone as sufficient therapy, tend to show a moderately favorable response to both drug *and* placebo.

For proven effectiveness against excessive, obstructive anxiety

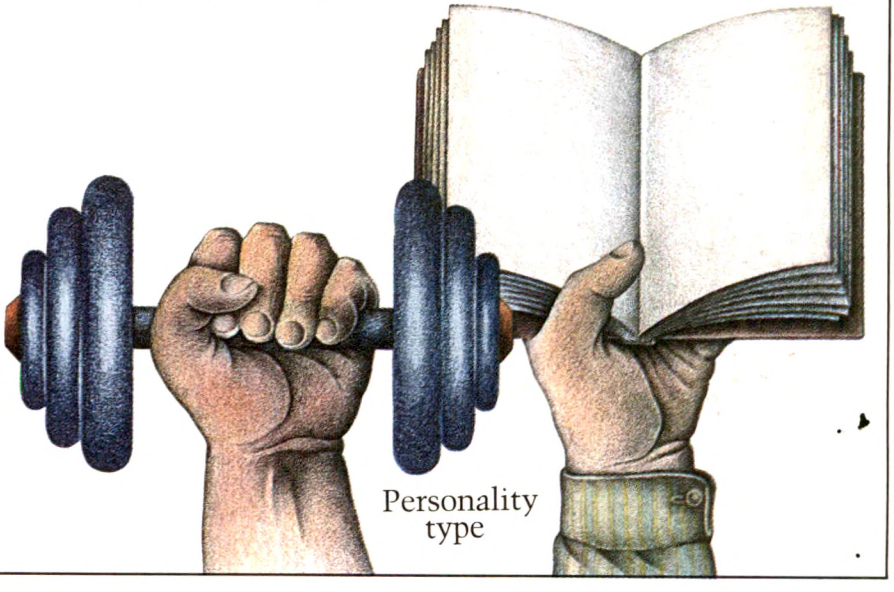


adjunctive



ROCHE **Librium®**

(chlordiazepoxide HCl)

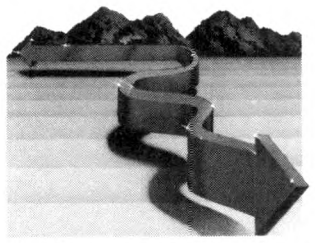


10 mg, 25 mg capsules

Please see following page for summary of product information.

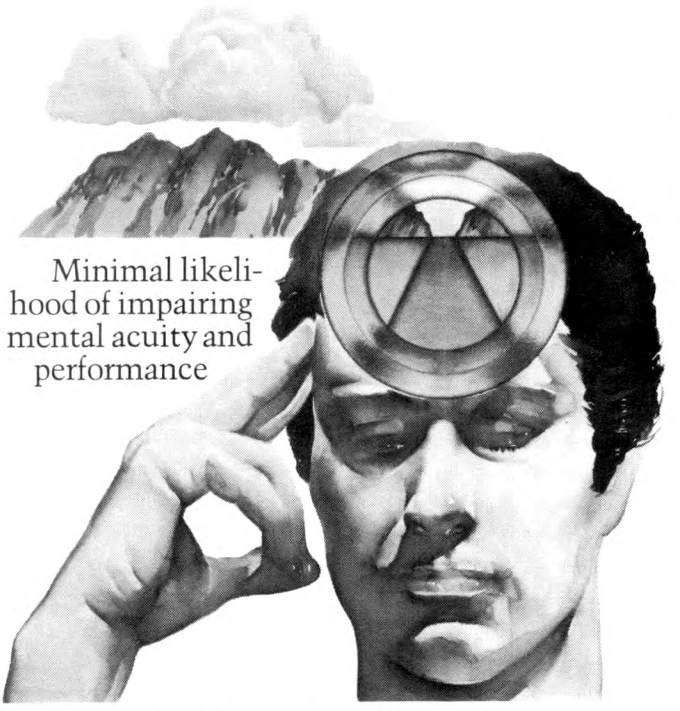
Degree of anxiety

Personality type



Effective adjunct in psychotherapy

Librium® (chlordiazepoxide HCl)



10 mg, 25 mg capsules/up to 100 mg daily in severe anxiety

While drowsiness, ataxia and confusion are the most frequently occurring side effects, physicians should be aware of the possibility of more serious reactions. Before prescribing, please consult complete product information, a summary of which appears below.

When anxiety has been reduced to useful, appropriate levels, Librium should be discontinued.

Wide margin of safety

Minimal likelihood of impairing mental acuity and performance

Dependable antianxiety action

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido – all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral– Adults:* Mild and moderate anxiety and tension, 5 or 10 mg *t.i.d.* or *q.i.d.*; severe states, 20 or 25 mg *t.i.d.* or *q.i.d. Geriatric patients:* 5 mg *b.i.d.* to *q.i.d.* (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) *Capsules*, 5 mg, 10 mg and 25 mg – bottles of 100 and 500; Tel-E-Dose® packages of 100. Libritabs® (chlordiazepoxide) *Tablets*, 5 mg, 10 mg and 25 mg – bottles of 100 and 500. With respect to clinical activity, capsules and tablets are indistinguishable.

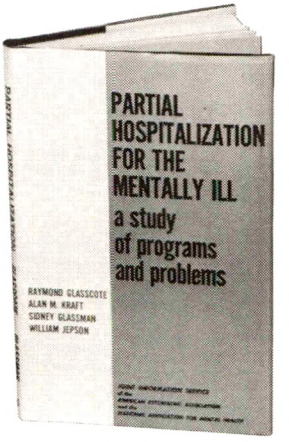
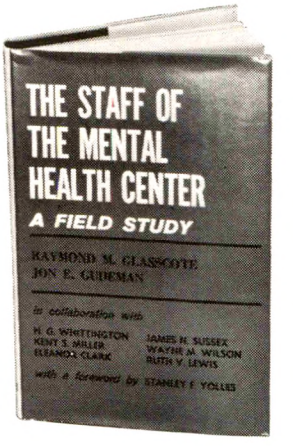
Four books that came before their time . . .



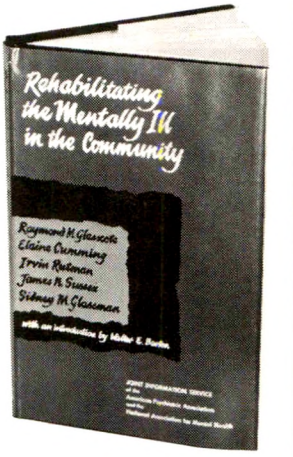
The APA JOINT INFORMATION SERVICE, trying alway to anticipate future needs and trends, expertly carries out field studies to develop information for program planning, for training—and for the practitioner who wants to be fully informed. The JIS saw years ago what most communities and community mental health programs are only now coming face to face with—that vast numbers of the mentally ill will need residential, vocational, and myriad other support services in the community as they are increasingly turned away from state hospitals and back to the cities and towns. Four publications assessing those needs, describing successful pioneering efforts, and providing practical hard-as-nails advice have been issued in the recent past. Unfortunately they are every bit as timely today as they were when they came off the press.

You need to know what they have to say. So we'll meet you part way: list price separately, $24; combination price, $18.50.



. . . concise, well-written, a model of medical reportorial writing, indispensable.

—AMERICAN JOURNAL OF PSYCHIATRY



. . . conveys its history, essential characteristics, its problems and goals for the future. . . . Definitive. . . .

—PSYCHIATRY

. . . deserves close study by those who are concerned with problems of organization within any psychiatric unit.

—BRITISH JOURNAL OF PSYCHIATRY

Once again, the Joint Information Service has published a useful documentary report that is readable and informative.

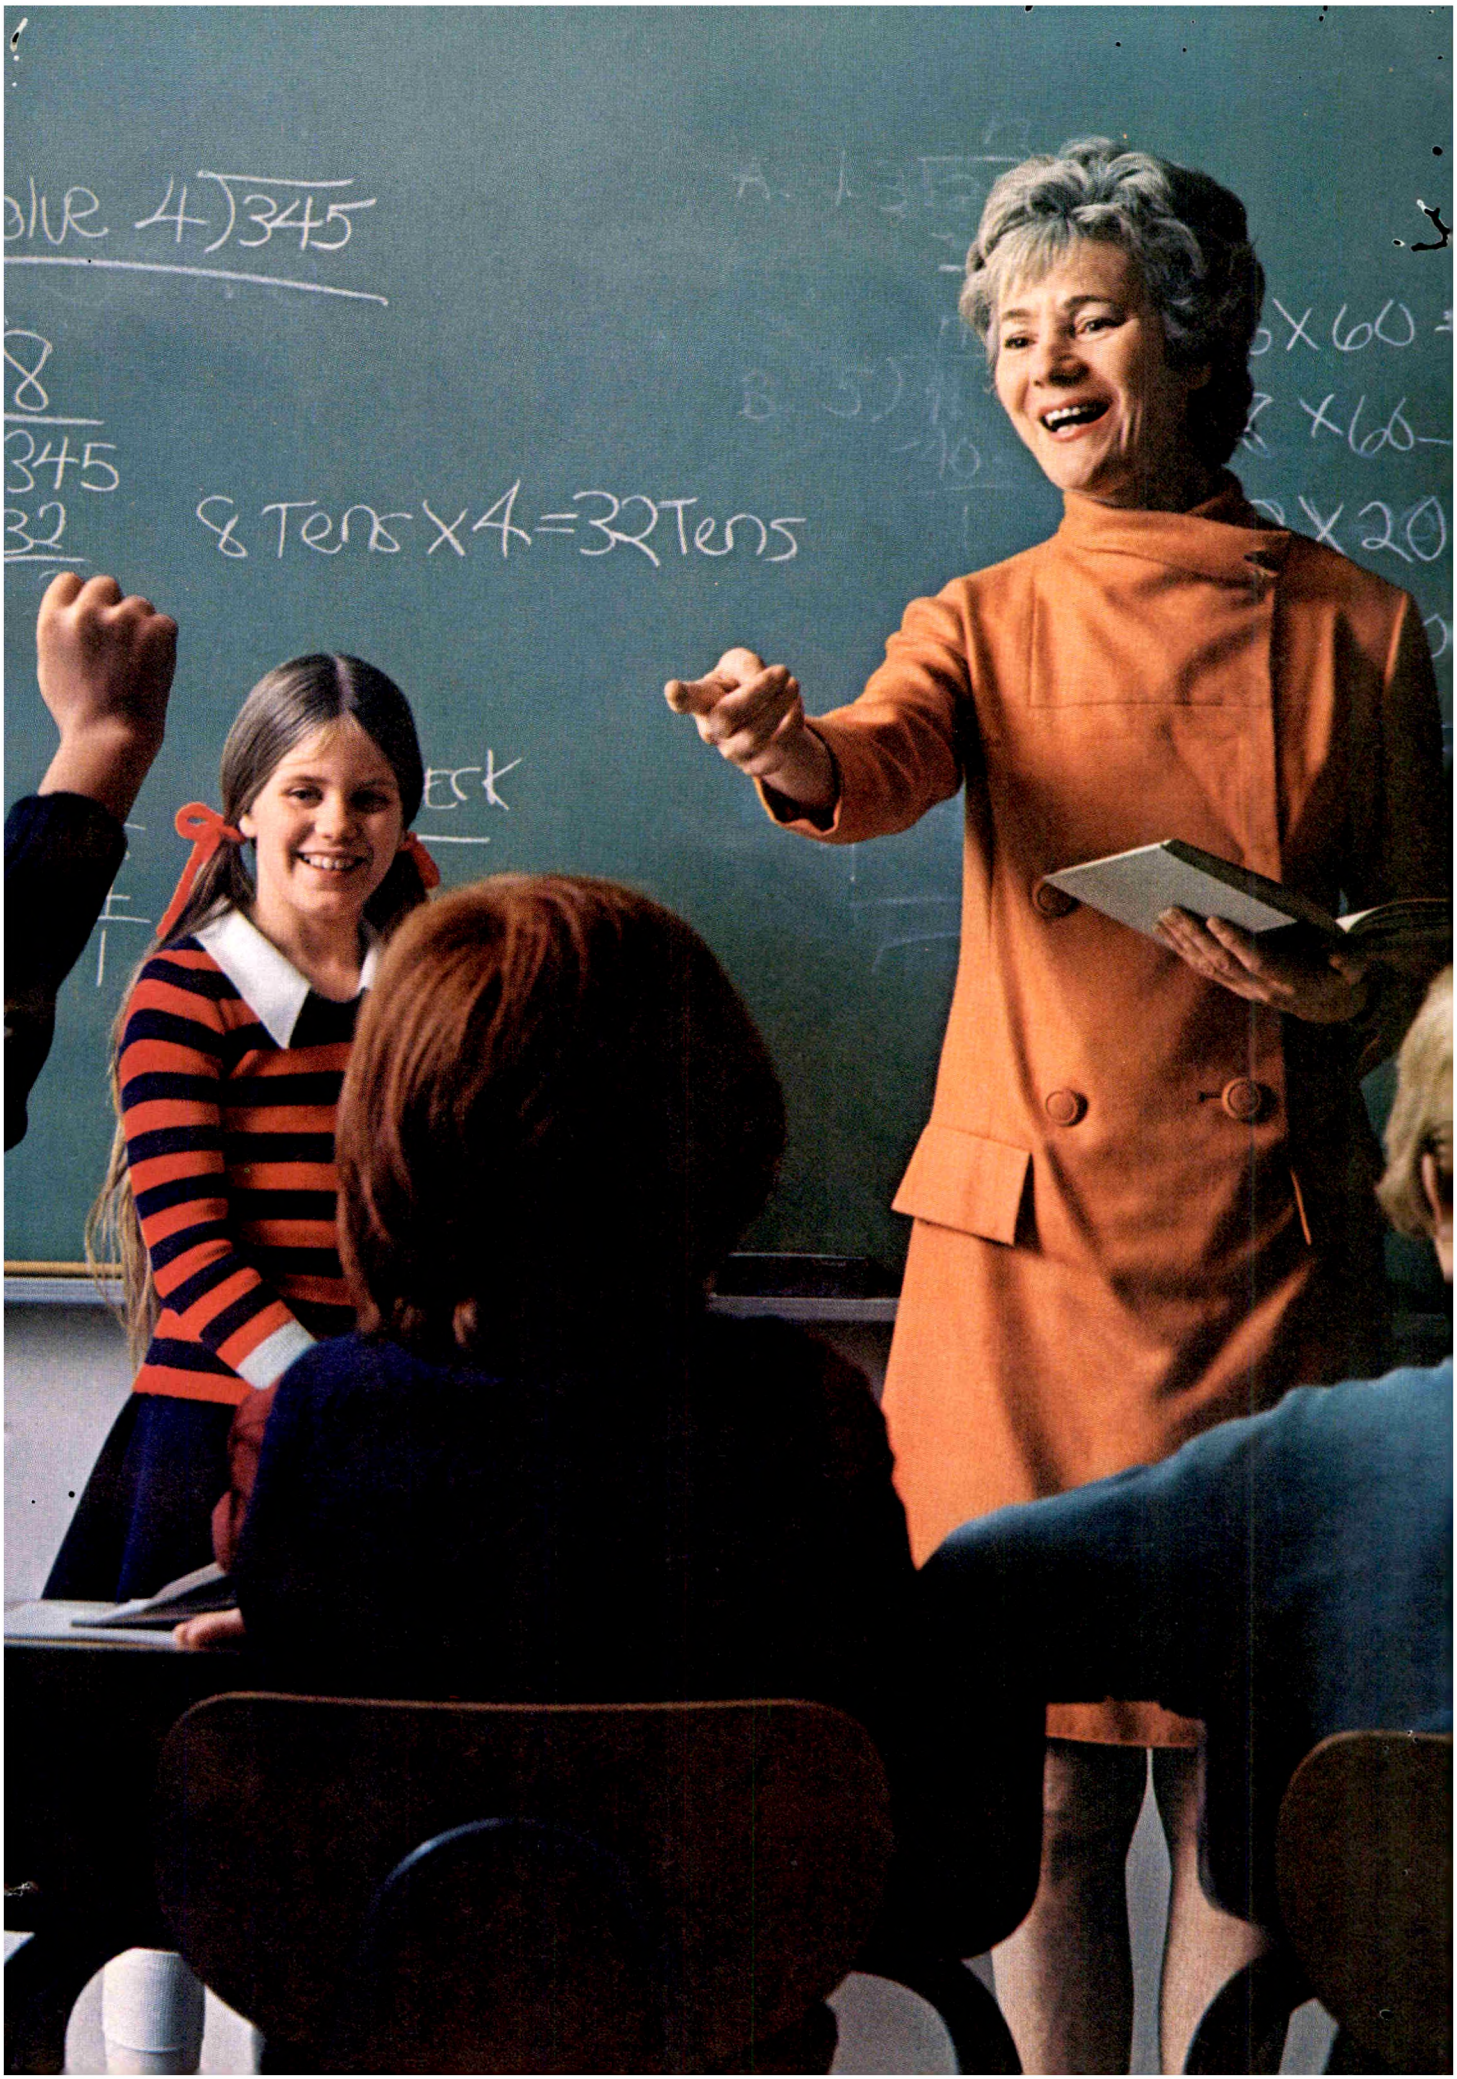
In the treatment of middle-age depression, there may be one thing to add...

Although the causes of depression in middle-aged women are varied, estrogen depletion is believed by many to be a significant contributing factor in depressions arising in the menopausal years.[1-7]

In the absence of a history of overt psychosis, estrogen replacement therapy alone, or in conjunction with antidepressants and counseling, may provide physiological and, in turn, psychological effect to enhance the total therapy.[7] Estrogen replacement has been noted to relieve the symptoms of estrogen-related depression in a relatively short time.[8] When used with antidepressants, estrogens may help bring about a generalized emotional improvement in patients, while waiting for initial response to slower acting antidepressants.



In many estrogen deficient patients, PREMARIN® (Conjugated Estrogens Tablets, U.S.P.) imparts a renewed sense of well-being. It helps alleviate depressive symptoms related to menopausal estrogen deficiency, while helping to identify those that aren't.

Crying spells, insomnia, fatigue, headache, feelings of weakness and other such symptoms may be relieved by estrogen replacement.[6,7] At the same time, the classic autonomic and metabolic symptoms of the climacteric may be controlled.[9,10]

PREMARIN® CONTAINS NATURAL ESTROGENS EXCLUSIVELY
(CONJUGATED ESTROGENS TABLETS, U.S.P.)

for estrogen-related depression

See last page of advertisement for prescribing information.

8 Tens x 4 = 32 Tens

PREMARIN®

BRAND OF

CONJUGATED ESTROGENS TABLETS, U.S.P.

for estrogen-related depression

contains natural estrogens exclusively

BRIEF SUMMARY (For full prescribing information, see package circular.)

PREMARIN® (CONJUGATED ESTROGENS TABLETS, U.S.P.)

Indications: Based on a review of PREMARIN Tablets by the National Academy of Sciences — National Research Council and/or other information, FDA has classified the indications for use as follows:

Effective: As replacement therapy for naturally occurring or surgically induced estrogen deficiency states associated with: the climacteric, including the menopausal syndrome and postmenopause; senile vaginitis and kraurosis vulvae, with or without pruritus.

"**Probably**" **effective:** For estrogen deficiency-induced osteoporosis, and only when used in conjunction with other important therapeutic measures such as diet, calcium, physiotherapy, and good general health-promoting measures. Final classification of this indication requires further investigation.

Contraindications: Short acting estrogens are contraindicated in patients with (1) markedly impaired liver function; (2) known or suspected carcinoma of the breast, except those cases of progressing disease not amenable to surgery or irradiation occurring in women who are at least 5 years postmenopausal; (3) known or suspected estrogen-dependent neoplasia, such as carcinoma of the endometrium; (4) thromboembolic disorders, thrombophlebitis, cerebral embolism, or in patients with a past history of these conditions; (5) undiagnosed abnormal genital bleeding.

Warnings: Estrogen therapy should not be given to women with recurrent chronic mastitis or abnormal mammograms except, if in the opinion of the physician, it is warranted despite the possibility of aggravation of the mastitis or stimulation of undiagnosed estrogen-dependent neoplasia.

The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, retinal thrombosis, cerebral embolism and pulmonary embolism). If these occur or are suspected, estrogen therapy should be discontinued immediately.

Estrogens may be excreted in the mother's milk and an estrogenic effect upon the infant has been described. The long range effect on the nursing infant cannot be determined at this time.

Hypercalcemia may occur in as many as 15 percent of breast cancer patients with metastases, and this usually indicates progression of bone metastases. This occurrence depends neither on dose nor on immobilization. In the presence of progression of the cancer or hypercalcemia, estrogen administration should be stopped.

A statistically significant association has been reported between maternal ingestion of diethylstilbestrol during pregnancy and the occurrence of vaginal carcinoma in the offspring. This occurred with the use of diethylstilbestrol for the treatment of threatened abortion or high risk pregnancies. Whether or not such an association is applicable to all estrogens is not known at this time. In view of this finding, however, the use of any estrogen in pregnancy is not recommended.

Failure to control abnormal uterine bleeding or unexpected recurrence is an indication for curettage.

Precautions: As with all short acting estrogens, the following precautions should be observed:

A complete pretreatment physical examination should be performed with special reference to pelvic and breast examinations.

To avoid prolonged stimulation of the endometrium and breasts in climacteric or hypogonadal women, estrogens should be administered cyclically (3 week regimen with 1 week rest period — withdrawal bleeding may occur during rest period).

Because of individual variation in endogenous estrogen production, relative overdosage may occur which could cause undesirable effects such as abnormal or excessive uterine bleeding, mastodynia and edema.

Because of salt and water retention associated with estrogenic anabolic activity, estrogens should be used with caution in patients with epilepsy, migraine, asthma, cardiac, or renal disease.

If unexplained or excessive vaginal bleeding should occur, reexamination should be made for organic pathology.

Pre-existing uterine fibromyomata may increase in size while using estrogens; therefore, patients should be examined at regular intervals while receiving estrogenic therapy.

The pathologist should be advised of estrogen therapy when relevant specimens are submitted.

Because of their effects on epiphyseal closure, estrogens should be used judiciously in young patients in whom bone growth is incomplete.

Prolonged high dosages of estrogens will inhibit anterior pituitary functions. This should be borne in mind when treating patients in whom fertility is desired.

The age of the patient constitutes no absolute limiting factor, although treatment with estrogens may mask the onset of the climacteric.

Certain liver and endocrine function tests may be affected by exogenous estrogen administration. If test results are abnormal in a patient taking estrogen, they should be repeated after estrogen has been withdrawn for one cycle.

Adverse Reactions: The following adverse reactions have been reported associated with short acting estrogen administration:

nausea, vomiting, anorexia
gastrointestinal symptoms such as abdominal cramps and bloating
breakthrough bleeding, spotting, unusually heavy withdrawal bleeding (See DOSAGE AND ADMINISTRATION)
breast tenderness and enlargement
reactivation of endometriosis
possible diminution of lactation when given immediately postpartum
loss of libido and gynecomastia in males
edema
aggravation of migraine headaches
change in body weight (increase, decrease)
headache
allergic rash
hepatic cutaneous porphyria becoming manifest

Dosage and Administration: PREMARIN should be administered cyclically (3 weeks of daily estrogen and 1 week off) for all indications except selected cases of carcinoma and prevention of postpartum breast engorgement.

Menopausal Syndrome — 1.25 mg. daily, cyclically. Adjust dosage upward or downward according to severity of symptoms and response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.

If the patient has not menstruated within the last two months or more, cyclic administration is started arbitrarily. If the patient is menstruating, cyclic administration is started on day 5 of bleeding. If breakthrough bleeding (bleeding or spotting during estrogen therapy) occurs, increase estrogen dosage as needed to stop bleeding. In the following cycle, employ the dosage level used to stop breakthrough bleeding in the previous cycle. In subsequent cycles, the estrogen dosage is gradually reduced to the lowest level which will maintain the patient symptom-free.

Postmenopause — as a protective measure against estrogen deficiency-induced degenerative changes (e.g. osteoporosis, atrophic vaginitis, kraurosis vulvae) — 0.3 mg. to 1.25 mg. daily and cyclically. Adjust dosage to lowest effective level.

Osteoporosis (to retard progression) — usual dosage 1.25 mg. daily and cyclically.

Senile Vaginitis, Kraurosis Vulvae with or without Pruritus — 0.3 mg. to 1.25 mg. or more daily, depending upon the tissue response of the individual patient. Administer cyclically.

How Supplied: PREMARIN (Conjugated Estrogens Tablets, U.S.P.) No. 865 — Each *purple* tablet contains 2.5 mg., in bottles of 100 and 1,000. No. 866 — Each *yellow* tablet contains 1.25 mg., in bottles of 100 and 1,000. Also in unit dose package of 100. No. 867 — Each *red* tablet contains 0.625 mg., in bottles of 100 and 1,000. No. 868 — Each *green* tablet contains 0.3 mg., in bottles of 100 and 1,000.

FIRST INTERNATIONAL SYMPOSIUM AND WORKSHOP On: SHORT-TERM DYNAMIC PSYCHOTHERAPY

MARCH 19-22, 1975

Sponsored by:

THE SHORT-TERM PSYCHOTHERAPY UNIT
of the
DEPARTMENT OF PSYCHIATRY,
THE MONTREAL GENERAL HOSPITAL
and the
DEPARTMENT OF PSYCHIATRY,
McGILL UNIVERSITY

With the participation of:
Dr. David Malan, Consultant
Tavistock Clinic, London, England
Dr. Peter Sifneos, Professor of Psychiatry
Harvard Medical School, Boston
Dr. M. Straker, Professor of Psychiatry
University of California, Los Angeles

To be held in **MONTREAL, QUEBEC, CANADA**

Audiovisual facilities are used throughout the four-day symposium and workshops. The aim is to demonstrate by use of videotapes the evaluation, criteria for selection of patients, techniques, process, and outcome of short-term dynamic psychotherapy.

For information and application forms, please write:
H. Davanloo, M.D., Director
External Services in Psychiatry and
Short-Term Psychotherapy Unit

QUESTION:

WHAT TRICYCLIC ANTIDEPRESSANT IS AVAILABLE AS AN ORAL CONCENTRATE?

A ANSWER: SINEQUAN® DOXEPIN HCl ORAL CONCENTRATE

10 mg./ml., 120-ml. (4-oz.) bottles

- ☐ Effective in the treatment of clinical depression/anxiety
- ☐ Eliminates potential for "cheeking" medication
- ☐ Colorless, tasteless following dilution
- ☐ Contains no alcohol or sugar
- ☐ Easily mixed with water or juices

BRIEF SUMMARY

Sinequan® (doxepin HCl) **Capsules/Oral Concentrate**

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* This drug has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: Usage in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan, however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan does exert a significant blocking effect. In addition, Sinequan was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). Sinequan (doxepin HCl) 25 mg. and 50 mg. also available in bottles of 5000. Sinequan Oral Concentrate (10 mg./ml.) is available in 120 ml. bottles with an accompanying dropper calibrated at 5 mg., 10 mg., 15 mg., 20 mg., and 25 mg.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630.
Stelazine® trademark licensed by SmithKline Corporation.

patients most in need of phenothiazines are often least able to cope with their side effects

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.

Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Tardive dyskinesia may appear in some patients on long-term therapy with phenothiazines and related agents, or may occur after therapy with these drugs has been discontinued; antiparkinsonism agents usually do not alleviate symptoms of tardive dyskinesia, and in some instances may aggravate or unmask such symptoms.

May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/ml

COGENTIN®
(Benztropine Mesylate | MSD)
helps alleviate most phenothiazine-induced extrapyramidal symptoms

In a recent study of 71 patients treated with antipsychotics, COGENTIN, administered in a double-blind manner in various dosage schedules, was found to be highly successful in relieving phenothiazine-induced extrapyramidal symptoms.[1] Patients experienced relief of such symptoms as facial and hand tremors, muscle weakness, sensations of psychic and motor excitation, and akathisia.

1. Neu C, Dimascio A, Demirgian E: Antiparkinson medication in the treatment of extrapyramidal side effects: single or multiple daily doses? Curr Ther Res *14*:246, May 1972.

impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.

Adverse Reactions: Adverse reactions may be anticholinergic or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Note: Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Patients with a poor mental outlook are usually poor candidates for therapy. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. When benztropine mesylate is used with levodopa the usual dose of each may need to be reduced. Certain extrapyramidal disorders that develop slowly, such as tardive dyskinesia, usually do not respond to the drug.

How Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000; Injection, containing 1.0 mg benztropine mesylate and 9.0 sodium chloride per ml, in 2-ml ampuls.

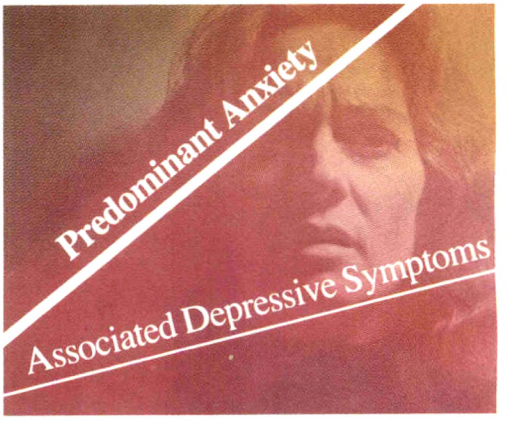
addendum

MSD
MERCK SHARP & DOHME

Facts about dosage schedules of COGENTIN (Benztropine Mesylate | MSD) in treating drug-induced extrapyramidal symptoms



In treating extrapyramidal symptoms due to central nervous system drugs, such as reserpine and phenothiazines, the recommended dosage of COGENTIN is 1 to 4 mg once or twice a day orally or parenterally. The tablet form should be used when patients are able to take oral medication.

When extrapyramidal symptoms develop soon after initiation of phenothiazine treatment, they are likely to be transient. One to 2 mg COGENTIN orally two or three times a day usually provides relief within one or two days. After one or two weeks, COGENTIN should be withdrawn to determine the continued need for it. If symptoms recur, COGENTIN can be reinstituted.

Certain extrapyramidal disorders that develop slowly, such as tardive dyskinesia, usually do not respond to COGENTIN.

For more detailed information, see full prescribing information.

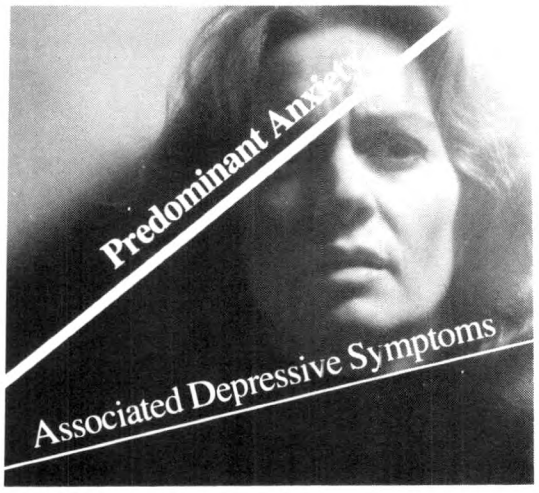
Neither separate nor equal.

Predominant anxiety is often associated with secondary depressive symptoms in a psychoneurotic complex that is important to recognize.

The psychoneurotic patient whose principal symptom is anxiety may also display secondary depressive symptoms. These depressive symptoms are not separate entities but, rather, part of a psychoneurotic symptom complex. As the anxiety responds to treatment with Valium® (diazepam), the depressive symptoms referable to it are also often improved.

The beneficial effect of Valium (diazepam) is usually pronounced and rapid. Improvement is generally apparent within a few days, although some patients may require a longer period. In addition, Valium is generally well tolerated but patients should be cautioned against hazardous occupations requiring complete mental alertness when taking this agent.

When the patient's anxiety and associated or accompanying depressive symptoms are intensified at bedtime, an *h.s.* dose added to the *b.i.d.* or *t.i.d.* treatment regimen can often relieve the symptoms and thus may encourage a more restful night's sleep.



For predominant psychoneurotic anxiety with associated depressive symptoms.

Valium® (diazepam)

2-mg, 5-mg, 10-mg tablets

Please turn page for a summary of complete product information.

For predominant psychoneurotic anxiety with associated depressive symptoms.

Valium® (diazepam)
2-mg, 5-mg, 10-mg tablets

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100; Prescription Paks of 50, available singly and in trays of 10.

THE NATION'S PSYCHIATRISTS— 1970 SURVEY

prepared by

Franklyn N. Arnhoff, Ph.D.

and

A. H. Kumbar

In this report, the survey data are organized under five general categories.

1. **Supply Characteristics** describes the survey sample in terms of its total number and the percent of response, APA members as well as the number who were in training and those psychiatrists with less than three years' training. It gives data on their age, sex, citizenship, race and work status.
2. **The Education and Training of Psychiatrists** provides data on the number in the sample who graduated from various medical schools by year, the number of years in training, whether the respondent is board certified, etc. All data are analyzed by sex so that this important dimension can be evaluated directly. Data on country of origin of medical school attended are also given for foreign medical graduates.
3. **Professional Activities of Psychiatrists** presents analyses dealing with various aspects of professional practice: where psychiatrists spend their time, how time is allocated, and what they do.
4. **Geographic Distribution of Psychiatrists** presents state totals for the identified manpower pool, along with ratios per 100,000 population.
5. **The Economic Issues** looks at such issues as the source of professional income and hours donated.

38 pages single copy **$3.25**

Please send me _____ copy(ies) of order #233, **The Nation's Psychiatrists—1970 Survey**, @ $3.25 per copy. (10% discount for 10 copies or more, and 20% for 50 or more).

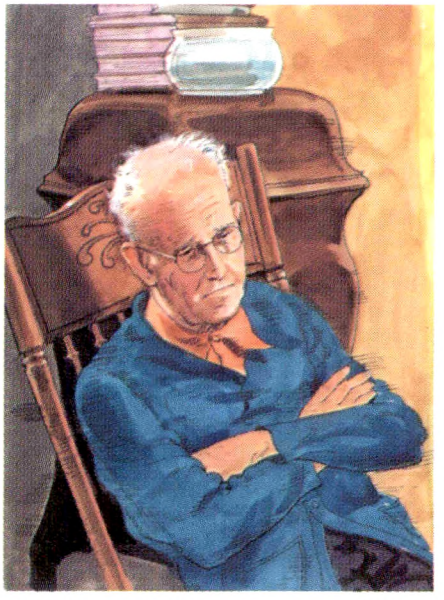
Adapting to age:

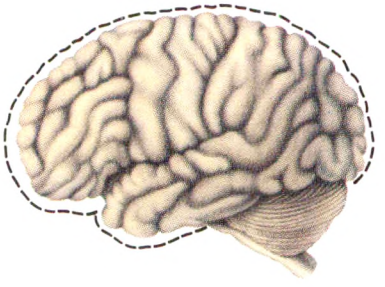
time and the mind

Aging successfully: is the goal just survival?



Popular belief would have it that "aging" and "existing" are the same, both marked by deteriorated ability—physical and mental. But is successful aging just existing?

Or is it making the most of one's abilities?



More than just surviving the changes and obstacles of old age, successful aging is *adapting* to the changes and *overcoming* the obstacles. Consider the very fortunate aging individuals who continue active, productive, even socially significant lives. Picasso, painting and sculpting until his death at the age of 91. Stokowski still conducting at 92. Margaret Mead, an active author and anthropologist at 73. Consider, too, those who lack prominence and popular acclaim, but still lead personally satisfying lives. Thus adding meaning to their prolonged existence by following interests and abilities.

How then, can some age so successfully, others less so, and still others merely survive? One reason: individual differences. Not only in abilities, but in opportunities and situations that can either nurture or suffocate ability.

Aging doesn't have to mean ailing bodies and failing minds. True, the cell loss of old age extends to the brain. But

the loss of brain cells doesn't invariably lead to loss of intelligence and alertness. For,

Although the decrease in brain volume is well known, enormous reserves of cerebral cells help compensate for loss with age. Disease and injury, more than advancing age, actually lessen cerebral capacity.

And lack of use contributes to the decline; mental and physical functions that are utilized tend to persist and those not utilized tend to disappear. So, if used, the mind often can remain alert. And, in fact,

Some now believe that intellectual decline can be minimal.

One theory isolates two basic types of intelligence: "fluid" and "crystallized." Both increase into adolescence, but fluid intelligence, formless and independent of education, begins to decline during the twenties. Crystallized intelligence—experience refined through education—continues to grow, and does not decline or even level off during old age. So, according to this theory, total intelligence changes qualitatively. Quantitatively, it remains relatively constant.

But we still see senility and seeming mental decline, sometimes caused by

injury to the brain from accident or a disease like cerebral arteriosclerosis. In some cases, the reason may be personality frustration even more than actual brain deterioration: a decline in *performance* generated by severe stress more than a decline in *cognitive ability.* Clinically significant anxiety, alone or associated with underlying organic disease, is common in the elderly, and can cripple the aged mind, and interfere with the adaptive process. But

When such anxiety is controlled the elderly patient may become more responsive to personal interests and social activities.

To therapy and counselling. To adapting to the changes of age.

If antianxiety therapy adjunctive to your counsel and reassurance is desirable, consider Serax (oxazepam). Serax has been found valuable, particularly in the older patient, in the management and control of clinically significant anxiety, tension, agitation and irritability.

Special care must of course be taken in prescribing antianxiety agents for elderly patients, especially where cardiac complications might ensue from a drop in blood pressure. And careful attention must be paid to dosage recommendations and follow-up observation.

More than eight years of clinical experience have shown Serax to be especially useful in many geriatric patients. Its dosage flexibility* generally permits adjustment to individual patient needs, making Serax a logical choice in the management of clinically significant anxiety in the elderly patient.

In Brief:

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease. Anxiety associated with depression is also responsive to oxazepam therapy. This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients. Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

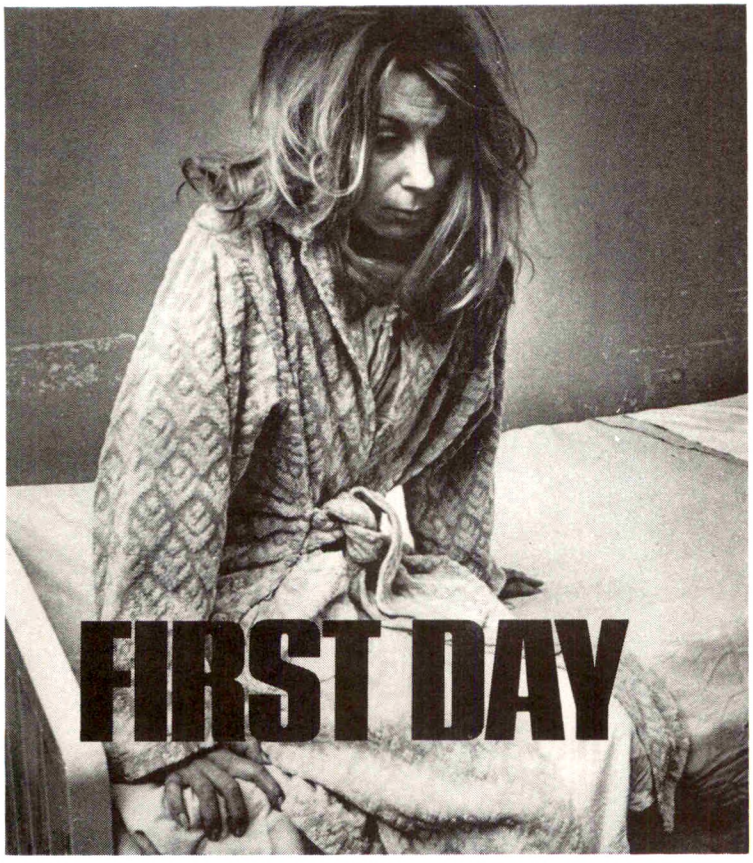
*See package circular for full prescribing information.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: Use in Pregnancy. Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance. Not indicated in children under 6 years; absolute dosage for 6- to 12-year olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.



Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

Wyeth Laboratories · Philadelphia, Pa. 19101

Wyeth

makers of Serax® (oxazepam)

for use in clinically significant anxiety

First day in the hospital and all efforts will be directed toward returning her to the community.

For psychotic patients with mixed anxiety-depression, Mellaril has been found useful to help patients participate more fully in the entire therapeutic program. Continued medication with Mellaril is often basic to helping patients prepare for and participate in outpatient treatment programs that bridge the gap between hospital and community.

With Mellaril, patients are generally alert and in better contact with reality and can more fully benefit from the entire therapeutic program. (In the hospital or out, even though Mellaril produces only minimal sedative effect, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, a distinctive feature of Mellaril is that extrapyramidal stimulation —notably pseudoparkinsonism—is minimal.

MELLARIL®
(THIORIDAZINE)

TABLETS: 25 mg., 50 mg., 100 mg., 150 mg., and 200 mg. thioridazine HCl, U.S.P.

helps in the management of psychotic patients with mixed anxiety-depression

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Defining Borderline Patients: An Overview

BY JOHN G. GUNDERSON, M.D., AND MARGARET T. SINGER, PH.D.

This review of the descriptive literature on borderline patients indicates that accounts of such patients vary depending upon who is describing them, in what context, how the samples are selected, and what data are collected. The authors identify six features that provide a rational means for diagnosing borderline patients during an initial interview: the presence of intense affect, usually depressive or hostile; a history of impulsive behavior; a certain social adaptiveness; brief psychotic experiences; loose thinking in unstructured situations; and relationships that vacillate between transient superficiality and intense dependency. Reliable identification of these patients will permit better treatment planning and clinical research.

IN 1953 KNIGHT NOTED that the term "borderline" was applied to patients who could not be classified in other ways, i.e., as psychotic or neurotic, hence making it something of a wastebasket diagnosis (1). No doubt much of the dissatisfaction with recognizing such a category, whether it is termed borderline or any of its alternative labels, stems from the wish to keep schizophrenia as a clearly distinct disorder. Yet despite this objection, its use has steadily expanded.

Stern (2) was the first to use the term borderline, but the real parentage for this unwanted category is traceable to the "as-if" personality described by Deutsch (3), the ambulatory schizophrenia of Zilboorg (4), and the latent schizophrenia as introduced and developed by Rorschach (5), Bleuler (6), and Federn (7). Latent schizophrenia was sanctioned by Bleuler in 1911 to classify persons whose conventional social behavior he felt concealed underlying schizophrenia. Ambulatory schizophrenia was subsequently offered by Zilboorg in 1941 to combat the therapeutic nihilism that clinicians felt the latent schizophrenia label implied. Deutsch's article on the "as-if" personality described persons whose superficial social appropriateness masqueraded highly disturbed personal relationships.

Before and even after Knight's paper popularized the term borderline, many other names were suggested and then silently retired in favor of the ever-widening use of this term. Among these are preschizophrenia (8), schizophrenic character (9), abortive schizophrenia (10), pseudopsychopathic schizophrenia (11), psychotic character (12), subclinical schizophrenia (13), borderland (14, 15), and occult schizophrenia (16).

The most serious competition in the nomenclature has come from the term pseudoneurotic schizophrenia. This term was particularly popular in New York because of the local influence of its originators, Hoch and Polatin and associates (17, 18). Hoch urged replacing the term borderline with pseudoneurotic schizophrenia, which defined a specific psychopathological condition characterized by the combination of panneurosis, pananxiety, and pansexuality together with symptoms of schizophrenia. The broadening of the concept of schizophrenia which followed in New York may be responsible for a discrepancy in diagnostic habits between New Yorkers and other American psychiatrists as well as the British (19). Yet this term, too, has given way in the most recent APA diagnostic manual (20).

Although the use of the term borderline has become more common, disagreement over its definition has not subsided but has merely been displaced and camouflaged. Many who accept this term now disagree about whether it refers to borderline patient (21), state (22), personality organization (23, 24), character (25), pattern (26), schizophrenia (27, 28), condition (29), or syndrome (30). The increasing frequency of "borderline" patients (31–36), the greatly expanding literature, and the existing confusion about diagnosis and treatment make it imperative that some method for defining the patient group be devised that is replicable and from which research can pro-

Based on papers presented by Dr. Gunderson and Dr. Singer at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Dr. Gunderson is Assistant Professor, Harvard Medical School, and Assistant Psychiatrist, McLean Hospital, Belmont, Mass. 02178. Dr. Singer is Clinical Research Psychologist, University of California, Berkeley, Calif.

ceed and conclusions can be generalized. In this paper we will attempt to survey the major relevant descriptive accounts of the borderline and to chronicle the common and discriminating features of these accounts.

Before we expand on these descriptive accounts, certain features about the literature itself should be noted. Since Knight's pivotal article appeared, there has been a large and still expanding descriptive literature on the borderline patient. There were approximately 25 articles on borderline patients up to 1955, and that number has doubled in the past 10 years. Nevertheless, there remains a confusing overlap and discrepancy among authors in their descriptive attempts to define borderline patients. While most authors pay lip service to the previous literature, they proceed to describe borderline patients anew without noting how their descriptions add to or simply repeat earlier contributions. It is not clear whether this provincialism stems from an unfamiliarity or an unspoken dissatisfaction with the existing literature.

In this article we will discuss the major descriptive accounts of the borderline syndrome. Clearly, not all of the writings are of equal importance. The work of some authors is extremely well known and widely quoted, while others' work is obscure and/or limited to a single publication. Certain writers attribute every imaginable trait to borderline patients, while others are quite selective in their descriptions. Furthermore, some authors expand or contract their definitions of borderline patients in later publications. In addition, some descriptive accounts are secondary or preliminary to a discussion of other issues, e.g., psychodynamics (37, 38), theory (27, 38), treatment (21, 31–33, 36, 37, 39–42), testing technique (43, 44), and schizophrenia (45). Yet in many the descriptive accounts are the primary goal of the paper (12, 17, 23, 29, 30, 46–49). Among the latter, only Grinker and associates (30) have undertaken a prospective and systematic collection of observations and data analysis.

Nevertheless, each of the authors cited has attempted to articulate his conceptualization of borderline patients and in so doing has implied either his agreement or disagreement with others. Taken in their entirety, these various views reflect the present clinical opinion about these patients. Any attempt by researchers to reliably define borderline patients should encompass these major clinical impressions. In this review, the most common and distinguishing characteristics will be identified, and a rational guide for standardizing clinical criteria for diagnosing borderline patients will be offered.

METHODOLOGICAL PROBLEMS

There are essentially three types of descriptive accounts: symptomatic and behavioral observations, psychodynamic formulations, and psychological test findings. Although these sources of descriptive data are parallel, they seldom seem touched or influenced by each other's proximity. This independence, or ignoring of other sources, arises in part from the different contexts in which the observations are made and reported. Symptom and behavior observations tend to be published in the psychiatric literature and are the purview of clinical researchers and of those involved in residential treatment. Psychodynamic formulations frequent the psychoanalytic literature and usually are developed within individual psychotherapeutic office practice. Finally, the psychological literature contains the accounts made of the borderline patient by psychologists who have administered controlled clinical testing procedures. In addition, the independence of these three groups no doubt grows out of a traditional suspicion each group holds for each other's methodologies. In any event, the psychologist tends to focus upon intrapsychic structure, the psychoanalyst upon theory and therapy, and the general psychiatrist upon diagnosis, prognosis, and outcome.

Clearly, the amount of structure provided by a setting in which the borderline phenomenology is observed will influence how these patients are described. For example, clinicians using psychoanalytic techniques and psychologists using the Rorschach test agree in emphasizing the major ego defects and primitive intrapsychic mechanisms and thinking found in these patients. Yet clinicians observing these patients in structured hospital settings or evaluating them with structured interview techniques emphasize their stable personality features and interpersonal patterns. Certainly the broad agreement among authors from all persuasions (4, 21, 22, 27, 29, 31–33, 35, 37, 39–41, 43, 50, 51) about the borderline patient's proclivity for regression in unstructured settings draws attention to the critical need to define the context in which the observations and descriptions of the borderline patient are being made. This propensity to regress when structure is low becomes an important and perhaps pathognomonic criterion for defining any sample of borderline persons.

The circumstances that lead the borderline person and his evaluator to meet are also important. For example, there appears to be a remarkable contrast between borderline outpatients voluntarily seeking treatment and borderline inpatients, who may be referred by others for treatment. A comparison of the observations made by Hoch and Cattell (17) with those made by Grinker and associates (30), the only authors whose descriptive data were collected in a systematic manner, sheds light on the influence of sample selection upon the conclusions reached about borderline patients.

Both research groups viewed schizophrenia as a distinct pathological condition and selected borderline patients who were free of overt schizophrenic symptomatology, such as clear-cut delusions and hallucinations, on the basis of their history and mental status examination. Hoch and Cattell further limited their sample to patients who presented mainly severe psychoneurotic symptoms, but who, on closer evaluation in psychoanalytic therapy and eventually in hospitals, revealed primary signs of schizophrenia in their thinking, feelings, and physiological functioning. Grinker and associates, on the other hand, selected patients on the basis of good functioning between hospitalizations and the presence of an ego-alien quality to any psychotic behavior. The diag-

nosis of borderline was made on outpatients, who were then hospitalized for participation in a prospective study. Thus Grinker and associates chose as their sample subjects with good premorbid features, and hospitalization was not a clinical necessity but rather for research purposes. It is not surprising, then, that their sample showed rare psychotic phenomena and developed virtually no schizophrenia during a five-year follow-up (52). In contrast, slightly more than one-fourth of Hoch and Cattell's hospitalized population later developed manifest schizophrenia (53).

It is clear that the initial selection of samples influenced the conclusion that Grinker and associates reached that borderlines and schizophrenics have separate and distinct disorders while Hoch and Cattell concluded that their patients were a subgoup of schizophrenics. It is somewhat like packing a suitcase and then being surprised later to find what is in it when it is opened.[1] Most authors choose to regard borderline patients as a group somewhere between, and perhaps including, both of these extremes. Thus the need for hospitalization is a critical variable in comparing samples. Borderline patients who are referred for hospitalization because of severe symptoms would be expected to be more disordered than those functioning as outpatients.

In summary, we have cited four major variables to be considered in any descriptive account of borderline patients: who is describing them, the methods used to collect descriptive data, the context in which the patients were observed, and how the sample was selected. Each has an important impact on the resulting description of borderline patients.

What follows is a selective review of the literature covering three major descriptive conceptualizations of the borderline: first, the literature on symptoms and behavior; second, the psychological test literature; and third, the analytic literature as it views ego functioning.

SYMPTOMS AND BEHAVIOR

In the descriptive behavioral and symptom literature for borderlines, a number of characteristics are repeatedly mentioned that can be grouped under the general headings of affect, behavior, and psychosis. Among the studies that have considered the behavior and symptoms of borderlines, the study by Grinker and associates (30) deserves special citation as the only prospective, systematic one. Despite the slanted selection of patients in that sample, the findings must be considered as the marker against which all other reports should be measured. It is thus of special value to compare the findings of Grinker and associates with those other descriptions based on purely clinical impressions.

[1]Grinker and associates noted that Hoch and Cattell tended to include more clearly schizophrenic symptoms in their later definitions of pseudoneurotic patients. Dyrud (32) has commented that Grinker and associates may have too readily dismissed the relationship between borderline and schizophrenic patients.

Affect

Of the four prevailing characteristics that Grinker and associates found in their borderline patients, two were qualities of affect.

1. *Anger.* "Expressed more or less directly to a variety of targets, anger seems to constitute the main or only affect that the borderline patient experiences" (30, p. 90). The expression of this anger—or the defenses against it—are a major discriminating feature used to identify four separate subgroups of borderline patients.

2. *Depression.* "Not the typical guilt-laden, self-accusatory, remorseful 'end-of-the-rope' type, but more a loneliness as the subjects realize their predicament of being unable to commit themselves in a world of transacting individuals" (30, p. 91). Grinker and associates pointed out that this depression was not present in their healthiest borderline group, which suffered instead from a clinging, childlike, anaclitic depression.

These conclusions by Grinker and associates are given substantial albeit inconsistent support by others. Some authors have noted the prevalence of anger but do not mention depression (21, 33), and vice versa (17, 36, 54). It seems likely that the confusion over the qualities of affect is traceable to at least two major sources. First, there is confusion about whether one is describing affects the patient presents with, affects that are covert, or affects that emerge in treatment. Second, as some authors have noted, the borderline patient's anger and depression have peculiar qualities.

How these two sources of confusion influence the descriptions of borderline affects becomes apparent when one examines some of the statements about depression in the literature. For example, there are frequent qualifying phrases used by those clinicians who note a predominance of depression. Cary (29) has noted that the borderline patient is characterized by a "sense of futility and pervasive feelings of loneliness and isolation" that he says do not constitute a "true" depression. Hoch and Cattell (17) stated that they found frequent secondary depressions due to the persistent illness in their pseudoneurotic patients, but that primary depressions were infrequent. Kernberg (23) noted the prevalence of depressive-masochistic character traits in some of his borderline patients but differentiated these from depressive symptoms. Further, he advised that depression "as a symptom should not be used directly as an indicator of borderline personality organization" but suggested that only severe depression approaching psychosis in the form of "ego depersonalization" should be a presumptive indicator for a diagnosis of borderline personality. Gruenewald (55) commented that there is often a "covert" depression that emerges later. Chessick (56) described a chronic "existential despair" in borderline patients.

Anger is less controversial than depression. Many authors have noted a prevailing anger in borderline patients. This one feature seems to have been used progressively to discriminate borderlines from the original description of the "as if" personality (3, 30) and from "schizoid" personalities (29), where withdrawal from

frustration is considered more characteristic. One author (57) felt that the borderline patient's anger is so prominent that he suggested changing the name to "choleric." Despite the apparent agreement about the prevalence of anger, such a broad range of behaviors is cited as being "angry" that a high degree of inference may be required. Some examples are hostility (50), rage reactions (31, 49), acting out (3), self-destructiveness (23, 31, 33, 58), detachment (59), mutism (33, 57), and demandingness (29, 57). Several authors have said that anger is not a presenting theme but one that emerges in the course of treatment (42, 50, 59). Kernberg (23) and Meza (57) speculated about excessive aggressive drive, while Modell (38) saw the anger as "mostly defensive."

In contrast, several authors have regarded anxiety as the typical affect shown by their patients. Hoch and Cattell (17) gave this anxiety the status of a "defining secondary diagnostic symptom." Although others (23, 32, 41, 47, 49) have also commented on anxiety in borderline patients, it is difficult in most instances to know if they are describing a symptomatic problem among borderlines or are making an inference based on a theoretical role given anxiety in personality theories.

Finally, another term frequently applied to borderline patients is anhedonia (32). In fact, there is considerable agreement that they lack a capacity for pleasure and rarely experience truly satisfied feelings. Their anhedonia has been discussed in terms of borderline dysphoria, unhappiness (47, 60), anguish (56), and lack of tenderness (3, 38).

In summary, the affective state of borderline patients is characterized by the prominence of anger and depression plus varying degrees of anxiety and anhedonia. If a generalization can be made, it is that these patients are not flat in their affect tone; they tend, in fact, to experience intense and variable affects, although this does not seem to include the experience of pleasure.

Behavior

Much of the literature on the treatment of borderline patients describes behavior during therapy, especially during hospitalization. Here we are interested in those behaviors which characterize borderline patients when they come for evaluation and that would therefore be used as criteria for making the diagnosis of borderline and in planning treatment. This is an important issue, since there may be a typical and highly distressing behavioral regression following hospitalization whose active prevention may be required from the start (21, 29, 31, 33, 35, 50, 61). Within the repertoire of hospital behaviors, such acts as window breaking, wrist slashing (31, 33, 58), and repeated overdosing (50, 62) emerge as quite specific to this kind of patient.

One historical factor, which led psychoanalysts to the conception of and interest in borderline patients as a distinct entity, was the discovery that many patients who by their histories and demeanors seemed relatively healthy underwent regressions on the couch. This disparity between good social behavior and poor intrapsychic structure has been mentioned repeatedly by both analysts (18, 48, 63, 64) and psychologists (28, 60, 65). What is meant by good social behavior seems to be good appearance and manners combined with superficial interpersonal relationships, and—more surprisingly—good functioning at work (12, 36, 42, 48, 60, 66, 67). The latter is surprising because this impression is noted almost in passing by many writers despite its apparent conflict with the behavioral record the patients have elsewhere in their lives. Schmideberg (47) took exception to this view. She described her borderline patients as marginal and transient in their work histories and cited their "sense of entitlement" as a source of their work problems. Grinker and associates summarized their follow-up data by saying, "Although gainfully employed and largely self-sufficient economically, the facts suggest that the group was occupationally and academically static at a fairly low level" (30, p. 132). Frosch (12, 66) noted that a borderline person may have a surprisingly stable work record when he is employed in a highly structured environment.

The characteristic most frequently and consistently ascribed to the behavior of borderline patients is that of impulsive and self-destructive acts. "Self-destructive" is used here to indicate a broad range of behaviors whose *result* is self-destructive although their intent or *purpose* is not. Examples include sexual promiscuity and perversions in search of affection (56, 68), self-mutilation with the goal of object manipulation (58, 61) or establishing self-identity (66), and addiction in search of escape (15, 32). Generally, borderline patients do not regard these behaviors as self-destructive, self-degradative, or guilt provoking. Although relatively little of the literature on borderline patients has dealt with actual suicide, repeated suicidal gestures and threats have been noted (50, 54, 57) and specific manipulative behavior attributed to such patients (69, 70).

Diverse sexual problems are attributed to borderline persons, but there is little agreement on their prevalence. Certain authors have noted a preoccupation with sex (17), and others have described polymorphous perverse sexuality (17, 23, 35, 46). Some authors (3, 12) have even included within the borderline category most persons with specific sexual deviances. Greenson (35) noted a "prominence of organ pleasures at the expense of object relations" among this group. Several authors (17, 41, 42) believe that these behaviors reflect a basic confusion in the sexual identity of the individuals.

The presence of obvious behavioral disturbances in a variety of spheres including drug use and sexual deviance often causes the borderline diagnosis to overlap with various character problem diagnoses in which chronic acting-out patterns such as antisocial, addictive, alcoholic, and homosexual behavior are seen. Because of this, Kernberg (71) has argued for a new classification of character types based upon what he believes are more fundamental personality features than behavior. He and many others have included a number of specific character disorders within the broader diagnostic category of borderline syndrome (21, 38, 41, 46, 47, 54, 68). Jan Frank (35) has sug-

gested that various acting-out behaviors provide outlets for many persons now diagnosed as borderline who previously would have become overtly schizophrenic. He and others (71, 72) believe that inadequate impulse control is the dominant ego defect in these persons.

One concludes that in considering the behavioral evidence for the diagnosis of borderline, a clinician should not be deterred by the presence of a stable work history or superficial social adequacy but should examine other areas, where he may often find evidence of impulsive sexual, drug-taking, or other activities whose results are self-destructive even though the patient's intent or purpose is not.

Psychosis

While there has been general agreement that borderline syndrome is a stable personality disorder (12, 23, 30, 33, 38, 39, 47), there is also widespread recognition that a number of these patients may develop psychotic symptoms (1, 17, 36, 39, 45, 46, 49, 51, 66, 73). Indeed, as indicated earlier, the borderline person's capacity to develop regressive psychotic symptoms may be a pathognomonic feature. Weiner would seem to concur with this conclusion in his review of the literature (28). However, there is a consensus that when psychoses do occur, they have the following differential features: 1) stress related (21, 23, 36, 43, 49, 68), 2) reversible (21, 30, 41, 49), 3) transient (12, 15, 30, 49), 4) ego-alien (1, 12, 30), and 5) unsystematized (23, 29, 30, 43, 45, 60, 74). Numerous authors have used some or all of these features to differentiate borderline psychoses from the psychoses of schizophrenia and other disorders (21, 23, 29, 30, 38, 45, 54, 66). Thus there is general agreement as to absence of stable or clear delusions or hallucinations, with only a few dissenting opinions (17, 33). Some authors have postulated that the borderline's psychoses occur in response to intolerable rage (29, 30, 41, 73).

Interestingly, despite the consensus about the vulnerability of certain borderline persons to psychotic-like episodes and regressions, only a few authors have viewed this as an essential feature of the borderline syndrome (1, 12, 45, 73, 75). Most authors have hastened to note that the occurrence of psychoses is the exception, not the rule (23, 29–31, 39, 46, 76). A few have taken a determined position that psychoses do not occur at all in borderline persons (33, 50, 63). At the opposite extreme, Hoch and Cattell (53) found that the psychoses in their sample of pseudoneurotic schizophrenic patients were not necessarily transient and reversible. A more recent report (77) suggested that the psychoses of this group cannot be differentiated from those of schizophrenics, and another (46) reported that they are brief and rare. This last report would thereby place pseudoneurotic schizophrenia within the mainstream of thought about psychoses among borderline persons.

There have also been widespread references to the similarity between the psychotic thought processes of borderline and schizophrenic persons. Some borderline persons demonstrate fears of being controlled (17), ideas of reference (38), externalization (1, 56), and other paranoid tendencies (12, 23, 56). Some writers have noted that they have vividly loose associations and other symptoms of formal thought disorder. For example, Knight (1) stated that loose associations can be detected by use of the Rorschach test and free-associative interviews. On the other hand, Grinker and associates (30) emphasized that they found no looseness of associations. (However, they did not use projective tests or free-associative interviews in their assessment of their patients.) Hoch and Cattell (17) took an intermediate position, stating that "approximate" or "parallel" associations are frequent. Thus there is little agreement among clinicians about the presence of thought disturbances in borderline persons. Some say there are none (23, 30), while others say there are many (1, 47, 50, 65, 73). It is clear that these differences result from problems in defining and assessing thought disorder as well as from the methodological problems cited earlier.

Some authors have underscored the frequent occurrence of disturbed states of consciousness. These peculiar ego states, which were first described by Deutsch (3), have been variously categorized as depersonalization, dissociation, and derealization (23, 29, 36, 45, 61, 66). They have been called borderline "states," to be differentiated from borderline "personalities." These states are seen as responses to anxiety (66), depression (23), and rage (29) and as prepsychotic experiences (3).

Separate from the purely clinical literature already summarized, a literature grew in the 1960s that recognized a vulnerability among borderline persons to psychoses when exposed to pharmacological stress, namely, that produced by marijuana (78), LSD (68, 79), and mescaline (68). These reports suggest that the borderline person is unique in his sensitivity to pharmacological stress. This special sensitivity or vulnerability seems to support Schmideberg's often quoted characterization of the borderline personality as "stably unstable" (47).

From the many foregoing clinical reports, which vary in their positions on whether psychoses occur among the borderline group, a series of clinical questions arise: Do all borderline persons have a vulnerability to psychosis even if they are not psychotic when assessed? Are most borderline persons free from psychosis throughout their life despite such a vulnerability? Clinicians are uncertain and divided over these issues. Grinker and associates (30) contended that psychoses occur in only one subgroup of borderline persons. Equally important, they are the only authors who have attempted to identify subgroups of borderlines who they contend will *not* develop psychoses. Other authors have implied or hinted that many or even most borderline persons could develop psychoses, given properly stressful circumstances. Parallel issues concerning the extent and type of their reality testing and the nature and type of their cognitive style will be considered in a later section of this paper.

To conclude, reports in the clinical literature generally agree that an undetermined number of borderline persons do develop psychoses in stressful situations. Moreover, when such psychoses occur, they are characterized by

their limited symptoms and limited duration. There are, however, few actuarial data on the prevalence of vulnerability to psychosis among borderline persons. Some authors have suggested that dissociative states may be quite marked in these patients.

INTRAPSYCHIC PHENOMENA

The psychological test literature devoted to characterizing borderline patients has generally been in agreement that they demonstrate ordinary reasoning and responses to structured tests such as the Wechsler Adult Intelligence Scale (WAIS), but that less structured tests such as the Rorschach reveal deviant thought and communication processes (27, 28, 43, 60, 74, 80–83). As in the clinical literature, most articles on which this conclusion is based are impressionistic. Their many methodological issues require attention before this broadly held viewpoint is accepted (6). The seminal contributions were made by Rorschach, Rapaport and associates, and Schafer, with subsequent authors generally being content to add confirmatory evidence.

Rorschach (5) and later Rapaport and associates (8) used the terms "fabulizing, combinatory, and confabulated" thinking to describe the propensities of borderline persons to overspecify secondary elaborations of their associations and to combine and reason oddly. They are prone to reason circumstantially rather than logically. Their separate perceptions tend to become intermingled and related simply because they occur close together in time or space. Borderline persons read more affective elaboration into their perceptions than others can validate, i.e., they tend to add too much and too specific affective material to simple perceptions. Other persons then have trouble accepting this affective meaning, although they might accept the same basic percept that the borderline person sees.

Rorschach, in 1921 (5), was the first to call attention to some seemingly adequately functioning persons whose responses to inkblot tests resembled those given by schizophrenic patients. He applied the term latent schizophrenic to those persons who had average surface behavior but Rorschach test features in common with schizophrenics, such as self-references, belief in the reality of the cards, scattered attention, variability in quality of ideas, and absurd and abstract associations.

It was Rapaport and associates (8) who first described the borderline person's intact performance on the WAIS and a pervasively odd Rorschach record; this has subsequently become an almost axiomatic diagnostic rule for later writers presenting single case studies. Although these authors defined two groups of what they called preschizophrenics, namely, the coarctated group and the overideational group, it has been largely the overideational borderline patient who is referred for psychological testing and upon whom subsequent literature has concentrated. Stone and Dellis (74) reiterated Rorschach's observation about the disparity between social functioning and thinking. They went on to confirm in a prospective study (74) Rapaport and associates' finding of a discrepancy between the Rorschach test and the WAIS in their evidence for pathology in borderline patients.

Schafer (82) introduced a third distinguishing feature about the disturbed thinking of borderline patients when he suggested that they are more comfortable about their bizarre and distorted thinking than are schizophrenics. Although Schafer's finding seems to differ from the general impression in the clinical literature that psychoses are ego-dystonic, it was later repeated in a report by Fisher (60).

In an interesting report DeSlullitel and Sorribas (84) compared the Rorschach test results of normal subjects, borderline persons, and creative artists. They found that the negative unpleasant content within "fabulized combination" responses by borderline persons distinguished them from the creative artists, who presented positive content within similar types of responses.

Gruenewald (55) reported on psychological test batteries given to 10 of Grinker and associates' original 51 borderlines five or more years after their discharge. She noted that based solely on test results, 2 would have been diagnosed as schizophrenic. However, when these data were combined with other information, the results were consistent with the borderline diagnosis and fit within the subgroups Grinker and associates had derived. She noted that "maladaptive primary process manifestations" were sometimes present in thought content and organization. Unfortunately, she made no mention of any discrepant functioning on individual tests.

In summary, borderline persons are believed to connect unrelated percepts illogically, overelaborate on the affective meaning of percepts, and give circumstantial and unpleasant associations to the Rorschach inkblots. This disturbed thinking may be more flamboyant and more ego-syntonic than that found among schizophrenic persons. Yet such borderline persons are reported to function adequately on the WAIS, showing few or none of the ideational deviances.

EGO FUNCTIONS

There are various ways to assess and classify ego functions. Thus it is difficult to select from the literature comparable descriptions of specific ego-function characteristics of borderline persons. However, two functions do emerge as particularly relevant to this group, namely, reality testing and interpersonal relationships. While the latter remains almost solely within the purview of clinical impressions, several approaches to evaluating reality testing have been made.

Reality Testing

Any discussion of psychosis is based upon the concept of reality testing. Frosch (12, 40) has stated that an intactness in reality testing differentiates borderline persons from schizophrenics. Distinguishing among reality testing, sense of reality, and relationship to reality, he

concluded that borderline and psychotic persons share a poor sense of reality and relationship to reality, but that the borderline person can test out his experiences whereas the psychotic cannot. In a panel report on the "as if" personality, a similar conclusion was reached about this subgroup of borderline persons (85). This position is akin to the frequent comments of several authors that borderline persons, when compared to schizophrenics, have more distance from their psychotic experiences and regard the episodes as ego-alien or ego-dystonic. Zetzel (21) added a twist to Frosch's viewpoint by stating that it is the capacity to reverse impaired reality testing, given a good situation (in treatment), that distinguishes borderline persons from schizophrenics.

A number of authors seem to agree with Frosch that reality testing is generally maintained in borderline persons (23, 30, 85). Wolberg (85) has stated that the reality distortions that do occur are defensive in nature and that the borderline person's actual perception of reality is always extant. However, Kernberg (51) has noted that "under special circumstances—severe stress, regression induced by alcohol or drugs, or transference psychosis"—they may lose this capacity. Kernberg and others have noted that these patients are prone to develop psychotic transference reactions. Of course, unless this feature is cited in the patient's history, it would not be of use in an initial diagnostic evaluation. Authors using psychological tests have assigned relatively greater importance to the vulnerability of the borderline person's reality testing to stress (31, 43, 60). Knight (1) noted the borderline person's inability to distinguish between dreaming experiences and reality. Hoch and Cattell (53) later drew a similar conclusion about the impairment in reality testing in their group of pseudoneurotic schizophrenic patients.

A number of authors have emphasized that reality testing should not be viewed as a phenomenon that one has or does not have but, rather, that there is a spectrum of reality testing (1, 16, 38, 50). Modell (38) and others (21, 23) have discussed the borderline person's reality testing problems in the context of self-object differentiation. Modell noted,

> The testing of reality depends upon the fact that in the ego's growth a distinction has been made between self and object .... there are degrees of alteration of this function of testing reality that correlate with the degree to which self and object can be differentiated .... the borderline transference is based on a transitional object relation where there is some self-object discrimination, but where this discrimination is imperfect. (38, p. 228)[2]

Such a graded view of reality testing helps to reconcile certain discrepancies noted earlier among authors who have presented contradictory views of reality testing in borderline persons.

As Hurvich (86) has pointed out, there is a need for quantifiable measurements of this ego function, which could be used to evaluate whether and to what extent impairment exists. Although Grinker and associates (30) included "relation to reality" as one of the seven ego functions they intended to evaluate in their borderline patients, they did not include any instruments to measure this directly. Their evaluation was based on behavior that was generally labeled as "positive" or "negative" and upon ratings of perception devised from global judgments of the patient's awareness of self, others, time, events, and things. These assessments did not give any consideration to latent vulnerability to disruptions in reality testing. Further, their validity as reflections of reality testing is not always obvious. Grinker and associates seemed aware of these problems and did not draw any definite conclusions about the relationship to reality and the capacity for reality testing in their sample. Until instruments or methods of measuring reality testing are developed, the literature on borderline persons will continue to reflect the ambiguity of the concept, and clinical impressions will be subject to the unstated and therefore unknown biases of the researchers.

At this time the consensus is that there is a definite impairment of reality testing in borderline persons, but it is not as severe as that in psychotic persons and, under most circumstances, is not apparent.

Interpersonal Relationships

A number of authors have pointed to borderline patients' style of relatedness as the most distinguishing diagnostic feature of this group. Zetzel (21) said that for the borderline patient in particular, "the kind of doctor-patient relationship that is established may prove to be a crucial factor in reaching a definitive diagnostic evaluation." This relationship is best illustrated by the following observations.

A frequently cited feature of the borderline patient's object relationships is a predictable superficiality and transiency (30, 32, 60, 87). Fisher (60) suggested that "superficiality in relationships" distinguishes borderline patients as a group from neurotic patients. Knight alluded to this somewhat differently by noting, "Other ego functions, such as conventional (but superficial) adaptation to the environment and superficial maintenance of object relationships, may exhibit varying degrees of intactness" (1, p. 6). This echoes the observation made earlier about the borderline person's surprising capacity for adequate social functioning but adds that this apparent behavioral normality may depend on superficiality. Dyrud (32) commented that case material cited by Grinker and others demonstrates more than anything else the remarkably short sequences of interactive behavior that these patients are capable of maintaining.

This quality of superficiality and transiency is supported and explained in some measure by the original formulations of the "as if" personality by Deutsch (3). Deutsch described the borderline person's interpersonal relationships as "plastic" and "mimicry." She stated that the "essential characteristic is that outwardly he conducts his life as if he possessed a complete and sensitive emotional capacity." Eventually, the absence of real emotional responsiveness leads to repeated dissolution of

[2]Burnham (61) has suggested that borderline patients frequently have pets or toy animals.

relationships. This disparity between adequate superficial relatedness and inadequate internal relatedness has been used to characterize borderline patients more generally (29, 30, 48–50, 60, 80). It may be attributable to a lack of coherent self-identity, which Grinker and associates (30) found in their sample and which other authors have also noted (1, 21, 23, 45, 49, 56, 66).

In contrast to the recurrent theme that borderline persons' interpersonal relationships are superficial and transient is the claim that they are prone to form intense, clinging relationships. Adler (31) stated that their "readiness to form rapid, intense, engulfing relationships" is what differentiates them from schizoid and schizophrenic persons. Similarly, Modell (38) stated, "My principal reason for considering this group homogeneous is that they develop a consistent and primitive form of object relationships in the transference." Grinker and associates (30) referred to this when they cited as one of the four identifying characteristics of borderlines "a defect in affectional relationships. These are anaclitic, dependent, or complementary, but rarely reciprocal." These accounts of borderline persons' intense relationships are underscored by the consensus that their initial relationships with therapists are dependent and demanding (12, 21, 23, 29, 31, 38, 50, 76). In addition, many authors have noted that the intense therapeutic relationship is characteristically devaluative and manipulative (21, 31, 38, 50, 57). The emergence of such angry behaviors may in turn lead to the repeated disruption of such close relationships (49, 50, 57). These qualities of the borderline person's close relationships may not be immediately discernible. Houck (50) pointed out that this initial deception can lead to later problems for unsuspecting therapists.

Thus in their everyday relationships borderline persons relate in a fairly normal but superficial and transient manner, while in their close relationships they become intense, dependent, and manipulative. In any event, these individuals are actively involved with other people and are not particularly socially withdrawn.

SUMMARY

In this paper we have surveyed the large literature of descriptive accounts of borderline patients. Within the major variations in these accounts we have attempted to identify certain themes and prevailing clinical impressions. We have discussed the four methodological issues that significantly influence the resulting descriptive accounts. Taking these methodological issues into account, we have identified a number of features that most of the authors believe seem to characterize most borderline persons. These features are as follows:

1. *The presence of intense affect.* It is usually of a strongly hostile or depressed nature. The absence of flatness and pleasure and the presence of depersonalization may be useful in differential diagnosis.

2. *A history of impulsive behavior.* This may take many forms, including both episodic acts (e.g., self-mutilation, overdose of drugs) and more chronic behavior patterns (e.g., drug dependency, promiscuity). Often the result of these behaviors is self-destructive although their purpose is not.

3. *Social adaptiveness.* This may be manifested as good achievement in school or work, appropriate appearance and manners, and strong social awareness. However, this apparent strength may reflect a disturbed identity masked by mimicry, a form of rapid and superficial identification with others.

4. *Brief psychotic experiences.* These are likely to have a paranoid quality. It is felt that this potential is present even in the absence of such experiences. The psychoses may become evident during drug use or in unstructured situations and relationships.

5. *Psychological testing performance.* Borderline persons give bizarre, dereistic, illogical, or primitive responses on unstructured tests such as the Rorschach, but not on more structured tests such as the WAIS.

6. *Interpersonal relationships.* Characteristically, these vacillate between transient, superficial relationships and intense, dependent relationships that are marred by devaluation, manipulation, and demandingness.

These six features provide a rational basis for diagnosing borderline patients. The criteria can be readily assessed during an initial evaluation. Further research is under way to evaluate the relative frequency and discriminating value of each of these features. From these studies a reliable system of diagnostic criteria can develop. It is hoped that such prestated and standardized means of identifying borderline patients will permit better treatment planning and clinical research on these patients to proceed.

Alcohol Use in the Army: Patterns and Associated Behaviors

BY JOHN F. GREDEN, M.D., SINAI I. FRENKEL, PH.D., AND DONALD W. MORGAN, M.D., D.M.SC.

The authors assessed by questionnaire the alcohol use of 1,873 U.S. soldiers in the United States and Viet Nam. According to operational definitions based on total ethyl alcohol consumption and several behaviors associated with drinking, 7 percent were classed as alcoholics, 5 percent as borderline alcoholics, and 24 percent as potential alcoholics. Contrary to popular stereotypes, there was a disproportionate number of younger and lower ranking soldiers in these three groups; there was also a positive relationship between drinking and use of illicit drugs across groups. The authors state that future studies of alcohol use should include determinations of total ethyl alcohol intake to permit generalizability of their results.

ALCOHOL USE AMONG SOLDIERS has caused periodic concern throughout modern military history. In 1895, for example, the Report of the Surgeon General of the Army reflected the disturbing facts that "17 [military] posts had more than 10 percent of their average strength under medical care for drunkenness" and that the hospital admission rate for alcoholism was "41.43 per 1000 strength" (1, p. 2). However, assessment of alcohol-related "costs" has always been complicated by the paucity of accurate prevalence data (2, 3). Official therapeutic response to the alcohol problem has fluctuated, perhaps in correlation to these deficiencies of information. Summarizing earlier studies, Fiman and associates (4) stated that "preventive and treatment programs under medical auspices have not been systematically developed, although from time to time there have been programs in each branch of the military."

In the late 1960's, as part of the research response to developing patterns of illicit drug use, there was greater investigation of alcohol use among military personnel. The findings of these studies precipitated renewed interest in alcoholism research, treatment, and outcome evaluation. In 1972, this burgeoning concern culminated in the establishment of a major Army-wide program to counteract alcohol abuse (5–7). In support of this program, we initiated an epidemiological study of basic patterns of alcohol and illicit drug use among two populations of functioning soldiers—one in the United States and one in the Republic of Viet Nam (South Viet Nam). Specifically, this paper emphasizes operational definitions of groups of alcohol users based on drinking patterns and correlated behaviors and examines prevailing hypotheses about military drinking patterns.

The traditional stereotype of the military problem drinker seems to have been one of a middle-aged senior enlisted man. According to West and Swegan (2), a major dilemma for commanders was the "40-year-old master sergeant with 17 years of honorable service, who has passed across the vague borderline between heavy drinking and chronic alcoholism, and who now is becoming less effective but is still a valuable person." Fiman and associates (4) and Cahalan and associates (8) provided some documentation for this stereotypic profile. Cahalan and associates also identified the factors of being single, separated, or divorced and having less than a high school education as significant correlates of heavy drinking, but they did not find race to be a definitive factor.

Another behavior examined in a variety of reports on both civilian and military populations is the association between illicit drug use and heavy drinking. Despite subjective disclaimers from both drinkers and drug users that the two patterns are unique, a number of studies have reported a positive relationship between heavy alcohol use and excessive use of drugs, including methadone (9–11).

To consider these various issues, we examined several prevailing questions about drinking patterns in the military: Is there any validity for the stereotype of the military problem drinker as a middle-aged senior enlisted man? Can a current high-risk typology for functioning problem drinkers be formulated? Are illicit drug use and alcohol use distinct and separate patterns (as youthful drug users in the military have frequently claimed when attempting to differentiate themselves from "juicers"), or do the two patterns coexist?

METHOD

In July 1972, we simultaneously administered questionnaires that could be keypunched to active-duty functioning soldiers in the United States and Viet Nam. The U.S. sample consisted of 863 enlisted men at Fort Lee, Va.—approximately 4 percent of the total post population. The Viet Nam sample included 1,010 U.S. enlisted

Dr. Greden is Assistant Professor of Psychiatry, Neuropsychiatric Institute, University of Michigan Medical Center, Ann Arbor, Mich. 48104. Dr. Frenkel is Director of Computer Support in Military Psychiatry and Dr. Morgan is Chief of Psychiatry Services, Department of Psychiatry and Neurology, Walter Reed Army Medical Center, Washington, D.C. 20012. Address reprint requests to Dr. Greden or Dr. Frenkel.

men stationed in Viet Nam—approximately 2 percent of the total American troop strength in July 1972. Only noncombat support troops (responsible for supplying, feeding, and maintaining installations and equipment for combat troops) were surveyed. In both locations, units were chosen randomly from available troop rosters solely on the basis of their availability during openings in our schedules. Cooperation was excellent: only five individuals in Viet Nam and two at Fort Lee chose not to participate in this voluntary survey.

Fort Lee is a military installation of approximately 15,000 active-duty personnel, located in central Virginia near Richmond and two smaller population centers. All respondents in the Viet Nam sample were located in the three primary areas of troop concentration at the time of the survey—Saigon, Long Binh, and Da Nang.

In both samples, respondents were surveyed in groups of 30 to 150 individuals assembled in or near their work or classroom areas. Command personnel were absent from the survey area during the approximately 20 minutes necessary to complete the form. During the introduction, we emphasized anonymity and our medical research orientation to help establish rapport. Each questionnaire consisted of 100 computer-tabulated multiple-choice items pertaining primarily to the individual's patterns of drug and alcohol use, demography, family and legal history, social and military adjustment, and need for treatment.

Classification Methodology

Two major factors were employed in the classification of respondents into subgroups: total quantity of ethyl alcohol consumed and the absence or presence of several behaviors characteristically associated with problem drinking.

To determine the quantity of alcohol consumed, each soldier's self-reported typical weekly consumption of liquor, beer, and wine was converted into total ounces of ethyl alcohol, the common denomination of alcoholic beverages.[1] The assumptions we used in these conversions were as follows:

1. Hard liquor contains 40 percent alcohol, and a shot (1 ounce) equals .4 ounces of alcohol.
2. Beer contains 5 percent alcohol, and one can (12 ounces) equals .6 ounces of alcohol.
3. Wine contains 12 percent alcohol, and one glass (3 ounces) equals .36 ounces of alcohol.

The quantities of alcohol consumed in the form of liquor, beer, and wine were summed to ascertain the individual's total weekly consumption of alcohol. In addition to this measure, selected behaviors used to define subgroups included several simple items often associated by other investigators with drinking: 1) drinking despite previous job trouble related to alcohol use, 2) drinking first thing in the morning at least once a week, and 3) drinking despite previous trouble in leisure activities due to alcohol use.

[1]In this report any reference to alcohol will mean ounces of ethyl alcohol converted from beverage alcohol.

Operational Definitions

The samples were arbitrarily divided into the five following mutually exclusive major groups on the basis of total alcohol consumption and related behaviors:

1. *Alcoholics.* This group included those respondents who consumed more than 50 ounces of alcohol a week (the equivalent of five commercial fifths of hard liquor) and those for whom drinking had caused job difficulties.
2. *Borderline alcoholics.* All respondents who drank 31 to 50 ounces of alcohol (the equivalent of three to five fifths of hard liquor) were included in this group.
3. *Potential alcoholics.* There were three subgroups in this category. The first consisted of respondents who drank 15 to 30 ounces of alcohol a week. The other two subgroups reported drinking less than 15 ounces of alcohol per week: one subgroup reported drinking first thing in the morning and the second subgroup reported drinking currently despite a history of problems in leisure activities due to drinking.
4. *Drinkers.* This group included respondents who reported drinking the equivalent of 1 to 14 ounces of alcohol a week without any history of alcohol-associated behaviors mentioned on their responses to the questionnaire.
5. *Rare or nondrinkers.* This group included respondents who reported that they drank rarely and those who totally abstained from alcoholic beverages.

RESULTS

There were striking similarities in the percentages of respondents falling in each of the nine subgroups for the Fort Lee and Viet Nam samples. For example, 4 percent of each sample reported drinking more than 50 ounces of alcohol a week and 3 percent described previous job trouble due to drinking, but reported that they continued to use alcohol. Percentages for each of the other seven subgroups were virtually identical for the two samples, and chi-square tests revealed no significant differences between the samples or any subgroups therein. Because respondents from the Fort Lee and Viet Nam samples reported such strikingly similar drinking patterns, they were combined and analyzed as one group.

To further simplify presentation, we will present data for only the five major groups rather than all nine subgroups. This is done because, as indicated previously, this paper focuses on patterns of alcohol use and associated behaviors for functioning soldiers in "representative" situations, rather than emphasizing comparisons between the Viet Nam and U.S. samples.

Distribution by Groups

According to our operational definitions, the distribution of the combined sample of 1,873 in the five major groups was as follows: alcoholics, 7 percent (N=131); borderline alcoholics, 5 percent (N=89); potential alcoholics, 24 percent (N=457); drinkers, 38 percent (N=712); and rare or nondrinkers, 26 percent (N=484).

TABLE 1
Comparison of Demographic Characteristics Among Operationally Defined Groups of Drinkers

Characteristic	Alcoholics (N=131)		Borderline Alcoholics (N=89)		Potential Alcoholics (N=457)		Drinkers (N=712)		Rare or Nondrinkers (N=484)		Total Sample (N=1,873)

Spends more than $5 a week on alcohol*	94	72	69	78	169	37	57	8	389	28
Drinks in morning at least once a week**	59	45	31	35	114	25	—	—	204	30***
Drinks hard liquor daily*	48	37	36	40	64	14	14	2	162	12
Misses at least one meal a week because of drinking*	63	48	41	46	105	23	64	9	273	20

*A 4 × 2 chi-square analysis (df=3) revealed significant differences for each of these items across drinking groups ($p<.01$).
**A 3 × 2 chi-square analysis (df=2) revealed a significant difference across drinking groups ($p<.01$).
***This percentage is based on a total number of 677 (rather than 1,389) because the 712 drinkers were excluded on the basis of operational definition.

Demographic Characteristics

Demographic characteristics for these five groups are given in table 1. Contrary to a common belief in the military, we found that noncommissioned officers over the age of 30 did not comprise a disproportionate percentage of the alcoholics and borderline alcoholics. In fact, a proportionately higher percentage of those under 20 years old and with ranks below sergeant were included in the groups with the heaviest alcohol consumption. Thirty percent of the alcoholics had not completed high school, compared with 16 percent of the total population.

In contrast to reported findings for illicit drug users, the demographic variables of race, marital status, and hometown population did not significantly differentiate among the drinking groups: between 68 and 73 percent of each of the groups were Caucasian, a range of 30 to 40 percent were married, and 37 to 44 percent were from towns of greater than 100,000 population.

Drinking Behaviors

To determine what types of alcoholic beverages each group drank in accumulating their total alcohol consumption, the percent drinking any liquor, beer, and wine, respectively, was obtained. Not surprisingly, a higher percentage of those designated as alcoholics reported drinking each of the three beverages (more than 90 percent were beer drinkers, 85 percent drank hard liquor, and 50 percent drank wine). Borderline alcoholics reported almost comparable patterns. Among the remaining three groups, the percent who consumed any hard liquor sequentially decreased, with only 48 percent of the drinkers reporting that they drank hard liquor.

Table 2 presents comparisons of drinking behaviors among the groups. The finding that more than half of the alcoholics said they started drinking before the age of 15 was striking; only 19 percent of the drinkers started before that age. A higher percent of the alcoholics also re-

ported drinking more since entering the Army. Alcoholics and borderline alcoholics consistently stated that they spent more money than the other groups on alcoholic beverages. This was, of course, consistent with operational quantity definitions. The finding that 28 percent of the alcoholics spent less than $5 a week on alcoholic beverages was initially puzzling, however. This could be partially explained by the fact that for five American dollars, a U.S. soldier in Viet Nam could buy approximately two and a half cases of beer or three fifths of liquor, and soldiers at Fort Lee could also purchase liquor at lower prices than in the civilian market. Thus, these soldiers could consume large quantities of alcohol cheaply. Forty-five percent of the alcoholics, 35 percent of the borderline alcoholics, and 25 percent of the potential alcoholics stated that they took a drink of alcohol the first thing in the morning at least once a week. Almost half of the alcoholics and borderline alcoholics also reported having missed one or more meals in the previous week because of drinking.

Family and Legal History

To compare drinking patterns with family history, we inquired about a variety of intrafamily relationships. Few significant differences were found among the groups in respondents' assessments of their own interactions with their parents and their appraisals of the relationship between their parents. A significant difference that did emerge was that a higher percentage of the alcoholics stated that their parents not only drank heavily but smoked heavily ($p<.01$, chi-square test). It should be noted that the percentages of each group reporting that their parents drank or smoked heavily were generally low, ranging from 20 to 3 percent across the groups. This family characteristic has been reported previously (12, 13).

Previous legal and social history also revealed that 44 percent of the alcoholics reported civilian convictions other than for traffic offenses, compared with only 16 percent of the total population ($p<.01$, chi-square test). A strikingly high proportion (14 percent) of the alcoholics had enlisted in the Army to avoid a jail sentence. With these previous patterns, it was not surprising that after entering the Army the alcoholics, borderline alcoholics, and potential alcoholics had significantly more administrative punishments and courts-martial than the other groups ($p<.01$, chi-square test).

Attitudinal Measures

In our investigation, we found that a significantly higher percent of alcoholics and borderline alcoholics said they were seldom busy on the job, found their jobs uninteresting, and were usually bored with their overall military situations ($p<.01$, chi-square test). A greater percent of alcoholics also reported feeling that their superiors showed little concern about the military mission, were not responsive to their individual needs, and that they subsequently did not feel free to talk with superiors about job considerations ($p<.01$, chi-square test). It was interesting to note that at least 50 percent of the alcoholics and borderline alcoholics, compared with 30 percent of the drinkers, felt that drinking on the job increased or did not change their ability to perform.

When asked whether they felt they currently needed help with a drinking problem, 12 percent of the alcoholics responded affirmatively. Only 4 percent of the borderline alcoholics and 3 percent of the potential alcoholics said they needed help. Essentially, this meant that 2.4 percent of the total population of 1,873 currently desired treatment for their drinking behaviors.

Use of Illicit Drugs

Table 3 clearly demonstrates a positive relationship between alcohol use and use of illicit drugs. For example, 68 percent of the 131 alcoholics reported previous use of marijuana. Among the other groups, the percentage of men reporting previous marijuana use tended to decrease as severity of alcohol use decreased, with only 39 percent of the rare or nondrinkers reporting this behavior. This pattern was consistent for each of the other drug types, including hallucinogens, stimulants, depressants, and heroin. An incidental finding was that heavier drinkers smoked tobacco more heavily than those groups with lower alcohol consumption.

Comparison of the Two Alcoholic Subgroups

As noted in our operational definitions, the alcoholics group consisted of two separate subgroups. Because of the implications of the label "alcoholic," we compared these two subgroups to determine if those respondents who consumed more than 50 ounces of alcohol a week were similar to those who did not consume this quantity of alcohol, but who reported previous job difficulties related to alcohol use. We found that these subgroups were essentially similar in most respects. The behaviorally defined subgroup drank less alcohol weekly than did the quantity-based subgroup. (This further explains why a higher percentage of the borderline alcoholics than of the combined alcoholics group spent over $5 a week on alcohol.) However, most of this subgroup did consume more than 30 ounces of alcohol a week, began drinking before the age of 15, drank more since they entered the Army, and drank in the morning at least once a week. Demographic characteristics and attitudes toward the military were similar for these two subgroups.

COMMENT

The major finding of this study was that a substantial 36 percent of the two samples we studied were classified as actual, borderline, or potential alcoholics. According to operational definitions, which relied primarily on quantity but also considered several simple behaviors associated with problem drinking, 7 percent of the population were categorized as alcoholics, 5 percent as borderline alcoholics, and 24 percent as potential alcoholics.

In 1972, Cahalan and associates (8) also reported that a high percentage of functioning soldiers had problems

associated with alcohol use. They described 35 percent of enlisted men as problem drinkers and 32 percent as heavy or binge drinkers. Because they employed different techniques, populations, and operational definitions, direct comparisons between this study and their findings were not possible, but the basic similarities are clear.

The first ancillary hypothesis tested in our study was not confirmed—namely, the stereotype of alcoholics in the military as primarily older, upper rank enlisted men. In this connection, it must be emphasized that respondents to our survey were functioning soldiers, not designated patients.

In response to the second question we studied, it was possible from our data to identify a current high-risk typology for problem drinking. Essentially, the soldier at high risk in this population was young (17–19 years old), low ranking, and less educated (i.e., had no high school diploma). This typology has previously been observed for both drug and alcohol use in military studies (10, 14).

The reemergence of drinking among young people has also been described recently in the mass media (15). Despite this recent emphasis on alcohol consumption among youth, military medical clinics and alcohol programs continue to describe alcoholics as older individuals (4, 16). This probably stems from the fact that it takes a number of years of heavy drinking combined with the aging process to produce the pathophysiology that prompts an individual to seek attention and permits a rigid diagnosis of alcoholism (17). Nevertheless, epidemiological profiles among functioning soldiers—rather than designated patients—emphasize an urgent need for innovative primary and secondary preventive programs for this youthful segment of the military population.

We found in examining our third question that heavy drinkers in our samples unequivocally reported greater use of all the major types of illicit drugs. A higher percentage of alcoholics than of the other groups reported use of marijuana, hallucinogens, stimulants, depressants, and heroin. A sharp distinction between "juicers" and "heads," therefore, was not confirmed by this study and appears to originate more from desired social identity of the users than from actual patterns of drug use.

To place these findings in proper perspective, it must be noted that our study was conducted during hot summer months, which may have greatly influenced consumption of alcoholic beverages, especially beer. Variables related to climate and season should undoubtedly be considered in future surveys of drinking behaviors. Also, the population we surveyed consisted of noncombat troops, and there may be differences between this group and soldiers in combat status. Furthermore, a relevant factor when considering age in any epidemiological study of drinking in the military is that selection procedures for advancement in the Army may skew the population by weeding out certain types of drinkers. For example, the heavy drinker without exceptional skills may be administratively or medically separated, or the disinterested heavy drinker may voluntarily terminate his military career.

Attempts to compare our findings with those from similar studies proved extremely difficult. Surveying the literature, we discovered that researchers have utilized a wide array of yardsticks in assessing drinking behaviors, a pattern that makes generalization and cross-validation difficult, if not impossible. Common denominators for problem drinking are genuinely difficult to agree upon. Admittedly, total quantity of ethyl alcohol consumed is just one parameter—and not always the most important—but it appears to be the only measure that can be universally applied in epidemiological studies of alcohol use. In future evaluations, innovative behavioral and psychological analyses should be encouraged, but a common feature of all studies, whatever their emphasis, might be the measurement of total quantity of ethyl alcohol consumed. Data from several large studies could then be accumulated and collapsed, distributions and standard deviations could be compiled, and some generalizability might finally be attained in studies of alcohol use.

Sensorimotor Functions and Cognitive Disturbance in Psychiatric Patients

BY GARY J. TUCKER, M.D., EDWARD W. CAMPION, M.D., AND PETER M. SILBERFARB, M.D.

The authors studied 109 consecutive admissions to an acute psychiatric unit in a general hospital to determine the relationship of specific sensorimotor impairments to cognitive disturbance. The results indicated a strong but not exclusive correlation between neurological impairment and thought disorder as well as between neurological impairment and schizophrenia. The theoretical and etiological implications are discussed, as well as the relationship of these findings to other variables.

SCHIZOPHRENIA REPRESENTS a psychopathological condition with clear cognitive disturbance (thought disorder). The present study investigates the role of specific sensorimotor impairments to cognitive disturbance. Although an attempt was made to examine schizophrenic patients specifically, cognitive disturbance is not exclusive to these patients (1). Consequently, a large group of patients was examined for this disturbance, but the major theoretical basis for this study relies primarily on studies of schizophrenic patients.

Neurological studies of adult schizophrenic patients have shown varied results, but if the criteria of soft or minor neurological signs (nonlocalizing) are used, in contrast to hard or major signs (localizing), there is evidence of neurological dysfunction in adult schizophrenia. Pollin and associates (2) and Hertzig and Birch (3) performed detailed neurological examinations on adolescent and adult schizophrenic patients and found more soft neurological signs in these patients than one would expect by chance. Increased soft neurological signs in schizophrenic patients have also been found by Kennard (4), Larson (5), and Rochford and associates (6).

Rochford and associates studied 65 hospitalized patients for the presence of the following soft signs: motor impersistence, stereognosis, graphesthesia, extinction to bilateral simultaneous stimulation, bilateral marked hyperreflexia or hyporeflexia, coordination defects, disturbance of balance and gait, sensory abnormalities, movement disorders, speech defects, abnormal motor activity, auditory visual integration, choreiform movements on the adventitious motor overflow tests, and cranial nerve abnormalities (such as slight aniscoria, esotropia, eighth nerve deficit not proven audiometrically, and mild visual field and retinal defects). Hard signs consisted of localizing findings of CNS abnormality such as lateralizing cranial nerve findings, pathological reflexes, unilateral sensory deficits and movement disorders, and unequivocal abnormal electroencephalograms. Rochford noted that neurologic abnormality was found in 36.8 percent of all patients studied, a finding significantly different from a control population of normal subjects. Interestingly he found no neurological abnormality among patients with affective disorder. The neurologic soft signs were found in a significantly greater number of the schizophrenic patients (65.5 percent) (6). Pollin and associates (2) noted that 72.5 percent of their schizophrenic patients had at least one sign; this percentage compares favorably to 65.5 percent in the study by Rochford and associates.

The high incidence of soft neurological signs in schizophrenic patients is difficult to ignore. The most frequent types of neurologic abnormality in the schizophrenic patients were defects in stereognosis, graphesthesia, coordination, and balance and gait and some movement disorder other than choreoathetosis. There was also some difficulty in auditory-visual integration of perceptual stimuli that may relate in part to the cognitive defects often evident in schizophrenic patients.

This study attempts to study the relationship between cognitive disturbance and sensorimotor functions and to evaluate whether this association is exclusive to patients with a schizophrenic diagnosis or whether there is a stronger relationship between sensorimotor impairment and cognitive disturbance than previously believed.

METHOD

The sample consisted of 109 consecutive admissions to the acute inpatient service of the Dartmouth-Hitchcock Mental Health Center during a six-month period (July to December 1972). The average age of the 109 patients was 32.9 years; 74 (68 percent) were women and 35 (32 percent) were men. They had an average of 12.9 years of education. All patients admitted to the inpatient service were tested except those who had a history of alcoholism, clear-cut neurological illness, treatment with ECT, or toxic psychosis or were below the age of 16 years or above the age of 60 years. To avoid some of the problems of diagnosis, the patients were classified as schizophrenic or nonschizophrenic on the basis of their scores on the

Revised version of a paper read at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

Dr. Tucker is Professor and Dr. Silberfarb is Assistant Professor, Department of Psychiatry, Dartmouth Medical School, Hanover, N.H. 03755. At the time of the study, Dr. Campion was a medical student at Dartmouth Medical School; he is now an intern at Cambridge City Hospital, Cambridge, Mass.

Schneider First Rank Symptom Scale (7) and the New Haven Schizophrenia Index (8). Their premorbid social behavior was determined by the use of two scales, the Phillips Prognostic Rating Scale (9) and the Klein Scale of Asocial Behavior (10). Other data collected included the Spitzer scale for psychiatric symptoms (11), routine developmental data, neurological history, and medications used (past and present). These interviews were performed by a separate clinician.

Shortly after admission, a separate tester who had no knowledge of the patient's history or diagnosis administered the Goldstein-Scheerer Object Sorting Test to each patient to assess cognitive disturbance. An experienced neuropsychological technician, who was unaware of the other results, gave standard tests for finger agnosia, finger-tip writing, and tactile form recognition (12, 13) and the Halstead Tactual Performance Test (14) for tactile performance. Patients were tested as soon after admission as possible (usually within 72 hours) and generally showed excellent cooperation with these procedures.

The Goldstein-Scheerer Object Sorting Test was administered and scored in the same manner used in previous investigations (1, 15, 16). The total number of objects sorted in seven trials and the patient's reasons for the sorts were recorded. Each patient received an overall score from 1 (normal) to 5 (markedly abnormal) on scales for overinclusive, idiosyncratic (or bizarre), and underinclusive thinking. The two independent raters who scored the results showed an interrater reliability of 91 percent. A score of 4 or 5 on either overinclusive, underinclusive, or idiosyncratic scales was classified as thought disturbance.

An experienced neuropsychologist analyzed the performances on each of the four neurological tests. From a frequency analysis of the results and comparisons with normal controls, a scale was devised so that a score of 1 (normal) to 4 (most abnormal) could be assigned to performance on each test. These scaled scores were then combined to form the following neurological impairment index: normal, 0–6; possible mild impairment, 7–8; mild impairment, 9–11; and moderate impairment, 12–16. Appropriate nonparametric statistical analysis was applied.

RESULTS

Of the 109 patients, 65 (59.6 percent) showed evidence of abnormal cognition on at least one of the scales of the object sorting test (see table 1). The predominant disturbance was overinclusive thinking, evident in 51.3 percent (N=56) of the patients studied. Idiosyncratic thinking and underinclusive thinking were much less common; they were present in 12.7 percent (N=14) and 9.1 percent (N=10) of the patients, respectively. Forty-five patients or 41.3 percent showed mild to moderate neurological impairment. If those with possible mild neurological impairment were included, this number went up to 57 percent of the patients. As only those with overinclusive thinking manifested a statistically significant relationship with neurological impairment ratings (p=.02, Spearman rank correlation), the subsequent data analysis is based on the overinclusive thinking scores.

In addition to the correlation of overinclusive thinking and neurological impairment, neurological impairment ratings correlated significantly with increasing age, with both measures of schizophrenia (New Haven Schizophrenic Index and Schneider's First Rank Symptom Scale), and with the number of previous psychiatric hospitalizations (p=.02, Spearman rank correlation). It is of interest that neurological impairment did not correlate significantly with scores on the Klein Scale of Asocial Behavior or the Phillips Prognostic Rating Scale. The data for younger age groups (16 to 25 years) and older age groups (25 to 39 years and 40 to 60 years) indicate that neurological impairment increases with increasing age. There is no statistically significant difference in the neurological impairment index in the two older groups between those with or without cognitive disturbance. However, there is a statistically significant difference in the younger age group (16 to 25 years); those with cognitive disturbance had a much higher neurological impairment index than those without cognitive disturbance (8.4 versus 5.5, p=.03, Mann-Whitney u test).

There were no significant differences between those who manifested cognitive disturbance and those who did not in terms of neurological problems or indicators (e.g., past history of convulsions, head injury, stuttering, and trouble in school with either reading, writing, or arithmetic). Impaired performance on the tactile form test, finger agnosia, and finger-tip writing, but not on the tactile form recognition test, correlated significantly with overinclusive thinking (but this was not an exclusive relationship).

The significant correlation of both measures of schizophrenia are consistent with previously reported findings in schizophrenic patients, as noted above, and will be discussed more extensively in a subsequent report. However, although the schizophrenic patients comprised only 34 percent (N=38) of the total patient sample, they comprised 50 percent (N=22) of those patients with neurological impairments (N=45): 57.8 percent (N=22) of the schizophrenics (N=38) had mild to moderate neurological impairment (table 1); 68 percent of the schizophrenics with thought disorder had neurological impairments; 41 percent of the nonschizophrenics with thought disorder had neurological impairment; but only 25 percent (N=10) of the nonschizophrenic patients without thought disorder had neurological impairments. These results indicate a strong but not exclusive relationship between neurological impairment and thought disorder as well as between neurological impairments and schizophrenia (see table 1).

DISCUSSION

Both thought disturbance and functional neurological impairment are present in hospitalized psychiatric patients, and this relationship exists unrelated to diagnosis, occurring in both nonschizophrenic and schizo-

phrenic patients. Although thought disturbance as measured in this study was more common than would be expected, certainly the incidence of 41.3 percent of neurological impairment in psychiatric patients is even more surprising. However, the tests for neurological impairment and thought disturbance are very specific and precise measures of functions that are usually not evaluated carefully in routine clinical evaluation. These results are noteworthy because the criteria for neurological and cognitive impairment were stringent and biased toward the extremes of abnormal performance. The fact that only 36 percent of the sample by either diagnostic criteria or 22 percent by both were schizophrenic indicates that both these impairments occur in nonschizophrenic patients as well. Our findings of a high incidence of neurological impairment in schizophrenic patients is consistent with previous studies (2, 3, 6, 17–19).

To interpret these findings the following questions must be answered: Are the neurological impairments only a reflection of normal aging? Are the measures of cognitive disturbance and neurological impairment measuring the same parameters? What is the role of medications? Certainly one would expect increasing neurological deficits with increasing age. Our data reflect this in part but may indicate other factors also. The chronicity of the illness and the effects of repeated hospitalizations and their attendant treatments may be concomitants of age and thus confound this relationship. That neurological impairments are significantly related to previous hospitalizations also connotes some factor relating to chronicity or severity. The fact that the neurological impairment is significantly greater in younger patients with cognitive impairment also attests to some particular relationship between these factors. All of these findings (cognitive disturbance, neurological impairment, previous hospitalizations) may also relate to severity of illness. Lillistón (20), in an interesting study, noted that the schizophrenic patients who showed more evidence of organic dysfunction on psychological tests also have more psychiatric symptoms. Similarly, Kennard (21) noted that in those patients with EEG abnormalities there was a higher incidence of disordered thinking. Therefore, although age cannot be ruled out, it cannot be the entire explanation.

Certainly one must ask whether or not the sensorimotor tests used in this study and the object sorting test are not measuring similar functions. Most people consider the object sorting test a test of concept formation necessitating adequate vision and the ability to form operational concepts (22). In addition, this test requires a degree of visual form perception in the same way that the sensorimotor tests require tactile form perception, sensory integration, and speed of performance. However, it would still seem unlikely that in this case the tests used are tapping similar functions. The object sorting test as used here was scored primarily on the basis of the patient's verbal interpretation of their sorts, e.g., on their ability to form concepts about why they sorted in such a manner. It was not scored on the basis of number of objects handed over by the patient; instead, the patient handed over the objects and then was asked why he did this. His subsequent responses were then scored for the degree of overinclusive, idiosyncratic, or underinclusive thinking. The sensorimotor tests (the tactile form recognition, finger-tip number writing, tactile performance test, and finger agnosia) required almost no verbal behavior or concept formation. Rosenbaum (23) tested various psychomotor behaviors in schizophrenic patients. He noted that while the schizophrenics could be discriminated on the basis of their performances on these psychomotor tests, especially weight estimation, they could not be differentiated when other perceptual modalities, especially auditory functions, were tested. Consequently, it would seem unlikely that the psychomotor tests employed by Rosenbaum are evaluating precisely the same functions as the sorting tests used in this study.

Although the relationship of medications, which nearly all these patients were taking (95 percent), must be considered a relevant variable, some patients taking the same medications had no cognitive disturbance or neurological impairment. Previous studies (24–26) have shown that the use of phenothiazines tends to lessen cognitive disturbance. Small and associates (27), using the Halstead-Reitan battery to demonstrate the effects of various treatments including ECT, phenothiazines, and lithium, observed no change in serial testing other than improvement in most areas. Also, the specific incidence of impairment in the schizophrenic patients is strikingly similar to the findings of Rochford and associates (6), whose sample was tested prior to drug use.

IMPLICATIONS

Certainly the association of cognitive impairment and neurological disturbance is not surprising in itself, as this is quite common in organic brain syndromes (28, 29). However, these patients are not clinically "organic," but only on detailed testing show minor sensorimotor impairments that have not previously been associated with cognitive disturbances; in both schizophrenia and organic brain syndromes, cognitive or thinking disturbances are evident perhaps more than in any other clinical condition. It is unfortunate that under these rubrics, e.g., cognitive or thinking disturbances, many different and similar defects have been described, some of which supposedly differentiate the two conditions (loose associations, symbolic-logical defects, etc.), and some which overlap (concreteness, disorganization) (29). Several studies (22, 30) have noted that in formal testing some schizophrenics will manifest thought disturbance while others will not; therefore, the presence or absence of thought disorder may relate to an as yet unclear second factor. Perhaps the presence of neurological impairments, related either to those demonstrated here or to others, may be the necessary factor for the occurrence of thought disorder. Overinclusion was by far the most prominent thought disturbance noted in the present sample, both in the schizophrenic and nonschizophrenic patients. This type of thinking disturbance might be a more pervasive disturbance, prominent during many different types of cerebral or behavioral dysfunction, while the bizarre, idiosyncratic, and personalized responses could more often be related to specific types of schizophrenia or psychosis. It is also possible that the more idiosyncratic responses need a more directed or focused inquiry or even relate to emotionally laden interpersonal interactions. Sophisticated neurological and psychological examinations of patients manifesting various types of thought disturbance seem mandatory. More precise definitions of terms such as "thought disorder" and "neurological impairment" are also needed. Perhaps descriptions of supposed defects rather than the use of labels may be more important in communicating about and furthering our understanding of these conditions than the use of these (typically) personally defined terms.

The meaning of the relationship of these sensorimotor dysfunctions and thought disturbance is still unclear, regardless of their occurrence in schizophrenia. Are these incidental findings related to either the treatments or the chronicity of the illness and its subsequent social isolation and institutionalization, or are they basic to the illness process or common properties of people who develop schizophrenia or thought disturbance? Longitudinal studies are necessary to integrate and understand the diffuse array of neurological findings that seem to be consistently reported in schizophrenic patients. Many of the sensorimotor dysfunctions may relate to some disturbance in the relationship of the person with the world, or, more broadly, they may relate to the area of functioning we call cognition. If we consider schizophrenia to be primarily a defect in thinking, as many have, then some biological deficits in the mechanisms used to assimilate information from the external world would be consistent with the hypothesis.

Previous studies by Petrie (31), Houpt and associates (16), and Silverman (32) showed that schizophrenic patients tended to reduce incoming stimuli. These authors postulated that schizophrenic patients are defective in the processing of incoming stimuli and that psychiatric patients, particularly those with thought disturbance, have difficulty in integrating perceptual sensory inputs and in the processing of these stimuli. Although this theory is intriguing, many studies indicate a decrease in many cerebral functions, e.g., decreased vestibular responses to various stimuli, hyperregulation of the EEG, etc. (29). All of these cerebral functions and the neurological impairments we have noted may be related to a generalized process of cerebral inhibition leading to many of the symptoms of thought disorder, specifically psychosis.

CONCLUSIONS

A number of studies indicate an increased incidence of soft signs or central nervous system functional impairment in psychiatric patients, particularly schizophrenic patients. In this study we demonstrate a correlation between similar neurological impairments and cognitive disturbances. We have previously stated that the cognitive disturbance measured by the Goldstein-Scheerer Object Sorting Test occurred in nonschizophrenic patients also (1, 15). It is clear that there is a stronger association between cognitive disturbance and neurological impairment than has been previously noted, particularly with respect to overinclusive thinking. This association seems more important than the association with traditional diagnostic categories.

Utilization Review of Treatment for Suicide Attempters

BY LARRY KIRSTEIN, M.D., BRIGITTE PRUSOFF, M.P.H., MYRNA WEISSMAN, PH.D., AND DAVID M. DRESSLER, M.D.

The authors describe an effort to develop criteria for utilization review of treatment for suicide attempters. Explicit criteria proposed by a panel of experts as essential determinants for hospitalization of these patients were compared with actual clinical practice. It was found that according to the experts' criteria (which were operationalized into rating assessments), over half of the outpatient sample should have been hospitalized. After multiple regression analysis was carried out on the criteria, however, four predictors showed that only 20 percent of the outpatients should have been hospitalized. The authors discuss the issues these findings raise about the criteria of the experts, their utility for research, their validity, and their implications for utilization review.

UTILIZATION REVIEW, which is now a standard part of medical practice, has only recently been introduced into psychiatric care (1–4). The difficulties in monitoring the quality of psychiatric care are major. There is lack of agreement about what type of information is relevant, how the information should be collected and interpreted, and what the appropriate outcome measures are.

In 1969 the psychiatric utilization review and evaluation project (PURE) was undertaken by a group composed of members of the departments of psychiatry, epidemiology, public health, and sociology of Yale University and members of the psychiatric staff from the Connecticut Mental Health Center. This group began the task of developing a basic utilization review program for patient care evaluation in a community mental health center.

Various ways of approaching the problem of creating a mechanism for the continuous monitoring of the propriety, effectiveness, and quality of patient care services were suggested. They included the following: 1) development of screening devices to select cases for review; 2) development of adequate guidelines (or explicit criteria) by panels of experts for the evaluation of care; 3) development of more adequate instruments for data collection; 4) assessment of factors involved in the actual process of evaluation of care by the reviewing physician; and 5) use of epidemiological surveys and follow-up studies to monitor patient care beyond the period of the patient's institutional stay.

As part of the project various panels were formed, one of which was organized to develop criteria for evaluation of care given patients with suicidal behavior. This panel used the criterion-oriented approach described in detail by Tischler and Riedel (5). Based on a review of patients' charts and on their own clinical experience and knowledge of the literature, the panel developed implicit norms that were then translated into explicit criteria for the hospitalization of patients exhibiting suicidal behavior. They developed nine criteria for which suicide attempters should be hospitalized and conducted a prospective study to compare these criteria with actual clinical practice.

This paper has several purposes. We intend to describe the nine criteria and how they were translated into operationalized assessments that could then be studied, to test the validity of the criterion-oriented approach by comparing the explicit criteria for psychiatric hospitalization with actual hospitalizations, and to explore alternate ways of refining the explicit criteria so that they might be more suitable for utilization review.

METHOD

Treatment Setting and Criteria for Selection

The prospective study took place in New Haven, Conn., at the Yale-New Haven Hospital and the Connecticut Mental Health Center. The main source of patients was the emergency room of the hospital, which at the time of the study provided the main resource for acute treatment for suicide attempters in the New Haven area. The staff were linked with the emergency services of the adjacent mental health center. During the day, crisis patients might be seen at either resource; at night they were seen only in the emergency room.

The study included all patients aged 16 or over who

came or were brought to the emergency services with a history of a suicide attempt or a suicidal gesture within the past three days. A suicide attempt was defined as any intentionally self-inflicted injury (including self-injuries by ingestion) unless there was good evidence both in the circumstances and in the patient's statements that there was not even partial or ambiguous self-destructive intent. Lack of intent was not assumed merely on the basis of the patient's denial, absence of serious risk to life, or added manipulative elements. It was accepted in cases such as attempted abortion by pill ingestion and cases of compulsive minor self-mutilation. Cases of accidental self-injury in which unconscious self-destructive intent was suspected were excluded in our definition of a suicide attempt because the injury was not intentional.

Included in our definition were suicidal gestures in which initiating moves of a potentially self-destructive nature had been carried out even if there was no risk of significant physical injury, e.g., climbing on a bridge, toying with a gun, announcing intent to ingest pills but actually taking no more than one or two. Some kind of act was required; patients only complaining of suicidal feelings, no matter how intensely, were not included.

Screening Procedures and Sampling

Screening took place over a period of 25 weeks, from November 1970 to May 1971. During this time psychiatric residents were instructed to identify and record data on all eligible subjects appearing at any time of the day or night on all days of the week. As a check on this procedure a research assistant examined emergency room records and other admission records daily to identify missed subjects. The appropriate resident was immediately contacted and the relevant information obtained in the event of missed cases.

During the 25 weeks, 274 subjects were identified and at least some data were obtained on each of them. The average inflow was 11 cases a week. Twenty-five patients hospitalized for medical sequelae of suicide attempts were excluded from the study because the disposition choice was a medical unit, and one patient was excluded because of insufficient data. This left a sample of 248 suicide attempters. Characteristics of the sample and the methodology have been detailed elsewhere (6).

Data Collection

Data were collected primarily by the psychiatric resident who first evaluated the patient clinically. After pilot studies had been carried out a precoded data-recording form was devised.[1] This form contains 101 items, including sociodemographic status, previous history, details of the attempt, judged and acknowledged motivations, mental status, social circumstances, what treatment was instituted, and residents' feelings toward the patient. Definitions of items and anchor points for each item's description rating were given in as much detail as possible. Items were adapted from a variety of sources, particularly the Los Angeles Suicide Prevention Center Assessment of Suicidal Potentiality (7), and, for mental status, a modified version of the Hamilton Rating Scale for Depression (8).

The form was completed by the psychiatric resident during or immediately after the initial interview with the patient. Almost all suicidal patients were seen by a psychiatrist when they first came to the emergency unit. For patients who were too physically ill or drowsy at this time, information was obtained after admission. Variables that referred only to the time of admission, such as mental status, were omitted. Thirty-two of the original 274 patients (11.6 percent) were discharged or died before information was obtained. For these patients, only basic sociodemographic data and treatment disposition were recorded. All of the data collected were recorded on precoded forms suitable for computer analysis.

RESULTS

Table 1 shows the criteria for hospitalization of patients with suicidal behavior developed by the expert panel as well as the translation of these criteria into operationalized rating assessments and operationalized criteria. These were administered as part of the resident's interview. Most of the criteria could be operationalized, but there was some redundancy.

Disposition Groups

The 18 operationalized criteria were rated on different scales, most of which were 4-point scales. Each scale was divided into two groups (e.g., high or not high, present or absent) according to the clinicians' judgment of the scale's reflection of the clinical situation. This dichotomization was done by a psychiatrist (L.K.) before the data were analyzed and was independent of the prospective study. A cross-tabulation of each of the 18 items was made with the three possible treatment dispositions.

Table 2 compares the operationalized explicit criteria with the treatment actually recommended. The items are ordered by their power to discriminate among the three groups.

Suicidal risk was the single most powerful item determining whether the suicidal patient was to receive a recommendation of hospitalization. It was found that 80.8 percent of the 121 patients who were hospitalized were considered high suicidal risks while only 25.7 percent of the 127 patients who were not hospitalized were considered suicidal risks. Eleven of the 18 items showed a significant prediction in the direction that the expert panel hypothesized. However, item 4b, "change from usual state," was a significant predictor in the opposite direction. A person having this symptom was more likely to have had an actual disposition of outpatient treatment than to have been hospitalized, although the experts judged that the presence of this behavior requires hospitalization.

The expert panel had agreed that the presence of any one of the criteria necessitated hospitalization. It is evident from the data shown in table 2 that all of the suicidal

TABLE 1
The Experts' Explicit Criteria, Their Operationalization into Rating Assessments, and Operationalized Criteria

Experts' Explicit Criterion	Operationalization of Rating Assessments*	Operationalized Criterion
1 A clear lethal suicide plan	1a How specific was the plan for the attempt and its execution?	Specific plan
	1b How intense has recent suicidal behavior been?	Intensity of attempt
	1c What were the social circumstances of the attempt?	Help sought
	1d Using all available data from the interview, what is assessment of the patient's intent to kill himself?	Serious intent
	1e Taking into account all of the evidence, what was the potential risk of the attempt to the patient's life?	Serious risk
	1f What were the medical effects of the attempt?	Major medical effects
	1g What is the patient's acknowledged overt intent in making the attempt?	Overt intent
2 A recent history of medically serious attempts	2a How many attempts has the patient made in his entire life, including this present episode?	Previous attempts
	2b How many suicide gestures has the patient made in his entire life, including this present episode?	Previous gestures
3 The presence of suicidal thoughts, gestures, or attempts in association with delusions or psychosis	To what extent does the suicidal behavior show the following motivations:	
	3a Bizarre motivation?	Bizarre motivation
	3b Depressive delusions?	Depressive delusions
	3c Paranoid delusions?	Paranoid delusions
	3d Thought disorder?	Thought disorder
4 A recent progression in seriousness of thoughts from suicidal thoughts to gestures	4a How rapid was the onset and development of the present suicidal preoccupation?	Speed of onset
	4b How much do recent suicidal feelings and preoccupation represent a change from the patient's usual state?	Change from usual state
	4c How long had the patient delayed between deciding to take his life and making the attempt?	Plans delayed
5 An expectation of hospitalization that cannot be changed during interview	5 What is assessment of the risk of suicidal behavior by this patient in the near future?	Suicidal risk
6 The presence of high-risk social circumstances, such as social isolation	6 What are the patient's living arrangements?	Living arrangements
7 A current, clear suicide attempt	7a through 7g: same as 1a through 1g	Same as 1a through 1g
8 Expression of strong suicidal thoughts with intent and without seeing any other way out	None	—
9 Expectation of change in behavior of significant others due to suicidal behavior not met; change cannot be accomplished appropriately	None	—

*The rating scales were generally 4-point scales with definite anchor points.

patients in this study had at least one of the symptoms and that according to the experts' criteria all 248 patients should have been hospitalized. Thus the 127 patients (51 percent) who were not hospitalized would have, by the experts' criteria, been subject to utilization review.

Multiple Regression Approach

In an effort to determine which combinations of items were most important to determine disposition in actual clinical practice, all 18 items were entered into a stepwise multiple regression analysis. Disposition was transformed into a dichotomous variable: the inpatients were given a score of 1 and noninpatients a score of 2.

Four items were determined to be significant by the multiple regression analysis: suicidal risk, thought disorder, serious intent, and major medical effects. These items accounted for 38 percent of the variance in predicting disposition. It must be noted that the suicidal risk item accounted for 31 percent of the variance; the value of the three additional items was therefore small. Using all four items, 51 of 248 patients (20.5 percent) were considered misclassified: 15 hospitalized patients who were predicted not to require hospitalization by the criteria and 36 nonhospitalized patients who were predicted to require hospitalization. Thus, using these four items, the charts of 51 patients would be open to utilization review.

TABLE 2
Comparison of Operationalized Explicit Criteria for Hospitalization and Actual Disposition (N=248)

DISCUSSION

Operationalizing the Criteria for Research

The findings show that the general guidelines developed by the experts could, with some exceptions, be operationalized and tested in a prospective study. Two of the nine criteria were not operationalized: criterion 8, "expression of strong suicidal thoughts with intent and without seeing any other way out," and criterion 9, "expectation of change in behavior of significant others due to suicidal behavior not met; change cannot be accomplished appropriately." However, operationalizing criterion 5, "an expectation of hospitalization that cannot be changed during the interview," called for a similar evaluation of the patient's expectations and future suicidal behavior. It would appear that the absence of operationalized assessments for these two criteria indicates a deficiency in the design of the prospective study.

There was some redundancy in the operationalized criteria, e.g., the "specific plan" criterion, and criterion 7, "a current, clear suicide attempt." This redundancy probably reflects the fact that the clinicians did not think in terms of operationalizing behavior. Greater attention must be paid to developing distinguishable explicit criteria so that translation into operationalized assessments will allow for testing of specific criteria with little overlap between variables.

Validity of Criteria

The validity of the criteria still remains a question. Was using the experts' opinion or using the clinical practice a valid approach? One way of determining the answer might be to look at the consequences of each approach. If the experts were correct, all of the suicide attempters should have been hospitalized and the 51 percent who were not hospitalized were misclassified. There is a body of literature (9–12) which agrees with the experts that all suicide attempters should be hospitalized. Two studies (9, 10) found that most attempters referred for outpatient treatment never actually begin treatment. Another study (11) showed that untreated suicide attempters are at higher risk for a future completed suicide than treated suicide attempters. In some parts of Great Britain it is the practice to routinely hospitalize all suicide attempters (12). Taken together, these studies suggest that outpatient treatment may be inadequate for suicide attempters.

If, on the other hand, the clinical practice not to hospitalize all 248 suicide attempters is valid, then the experts' criteria are too conservative. A number of problems could be seen in the British practice of hospitalization and in the experts' criteria. Of practical concern is the number of beds necessary to hospitalize all suicide attempters. Furthermore, a number of suicide attempters would be encouraged to identify with a sick, dependent role and look to hospitalization as an escape rather than try to cope with their conflicts. A third area of objection arises from the ethical and legal aspects of imposing hospitalization on a person who does not want it.

One way of determining whether or not the experts' criteria are valid would be a long-term follow-up study to see what happened to the 127 nonhospitalized patients in comparison with the 121 hospitalized patients. If the nonhospitalized patients had a poorer outcome (repeated suicide attempts and/or completed suicides), the experts' criteria should be considered more valid than clinical practice.

Implications for Utilization Review

The main purpose of this study was to develop criteria for utilization review of patients with a wide range of suicidal behaviors. Misclassified patients include those hospitalized patients who should not have been hospitalized ("overtreated") and those patients not hospitalized who should have been hospitalized ("undertreated"). According to the experts' explicit criteria, 127 of 248 patients (51 percent) were considered misclassified and should have been hospitalized. After multiple regression analysis, four operationalized guidelines determined that 51 of the 248 patients (20.5 percent) were misclassified: 15 (6 percent) were "overtreated," and 36 (15 percent) were "undertreated."

By refining the experts' criteria with multivariate techniques, the task of utilization review shifted from examining why 127 patients were not hospitalized to examining 51 charts. This seems to be a feasible task. Questions concerning the 15 patients who were "overtreated" would include whether they represent a discrete group with other characteristics that led to their hospitalization or whether they were truly a misclassified group. Similarly, it seems practical to begin reviewing the charts of the 36 "undertreated" patients rather than 127 charts and to focus on whether these 36 patients have characteristics which might explain their receiving less than adequate care. This is a particularly important group to examine in view of the high risk of a future successful suicide. Further work remains to be done on the application of the four criteria derived from the multivariate analysis to other treatment settings.

CONCLUSIONS

According to these results, the use of experts to develop guidelines for utilization review in psychiatry is feasible, at least with the treatment of suicide attempters. In general, criteria could be operationalized and tested. While the experts' criteria appear more conservative than actual practice, long-term follow-up studies are required before conclusions can be drawn. The combination of experts' criteria to develop baseline variables and multivariate analysis of the variables predictive of actual practice offers an approach to this complex problem.

ACKNOWLEDGMENTS

The authors would like to thank the panel members of the psychiatric utilization review and evaluation project, Yale University, who initiated the prospective study.

Other panel members involved in that study include Eugene Paykel, M.D., Nancy French, M.S., Carolyn Hallowell, M.S.W., Hal Mark, Ph.D., and Donald Shapiro, M.D. The authors would also like to thank the faculty and second-year residents in the emergency room of the Yale-New Haven Hospital who assisted in the data collection as well as Ms. Karen Fox for data collection and Ms. Phyllis Newberry for carrying out the data analysis for this paper.

Obstacles in the Treatment of Dying Patients

BY PERITZ LEVINSON, M.D.

Theory and practice in the management of the dying patient have moved forward in the past two decades. However, the author believes the benefits of this progress have not reached a large segment of the population of dying patients—those individuals who have a higher level of psychopathology or are from a lower socioeconomic group. Obstacles in the treatment of such patients are described and illustrated by case histories; the author makes specific recommendations related to the care of these more difficult cases.

THE TREATMENT of the dying patient has gained systematic attention only during the past two decades. Despite the brevity of this period, there have already been three distinct historic phases. During the first phase, well-integrated patients who generally qualified for psychoanalysis were studied. During the second phase, treatment of the dying patient was extended to a larger but still selective group of middle-class individuals. The current or third phase of modern thanatology is facing the challenge of bringing the treatment of the dying patient to all individuals regardless of psychopathology, socioeconomic status, race, or religion. In order to accomplish this, obstacles in the treatment of these dying patients must be carefully delineated and confronted. In this paper, I will describe these obstacles, provide illustrative clinical cases, and make recommendations for dealing with them.

REVIEW OF THE LITERATURE

The First Two Phases

The first phase in the recent history of treating dying patients coincided with the appearance of *The Psychiatrist and the Dying Patient* by Kurt Eissler in 1955 (1). Eissler's book was associated with a decided quickening of interest in thanatology. The treatment of dying patients recorded in this volume was careful, thorough, and well documented. A number of detailed clinical studies in this style followed (2–5), and landmarks were charted in the feelings of the dying patient, his methods of coping with death, and the relationship to his doctors. These studies dealt with only a small minority of the population of terminally ill individuals. These individuals were, for the most part, young, intelligent, cultured, mature, reality-based, and responsive, with high levels of frustration tolerance and good capacities for object relations. They did not display the characteristics of isolation, dependency, immaturity, distrust, superstition, and lack of education that frequently appear in the general population.

The second phase was exemplified in the work of Elizabeth Kubler-Ross, whose book *On Death and Dying* (6) appeared in 1969. This study, which took place at Billings Hospital in Chicago, sampled a highly religious middle-class group of individuals who were invariably mature, hard-working, self-sacrificing, verbal, responsible, family-oriented people with roots in the community. Like the cases in Eissler's book (1), these cases are not suitable as models for the treatment of the dying patient in the general population because they do not reflect the significant limitations in relatedness, emotional stability, intelligence, and accomplishment that are found in the general population.

The Third Phase: The Problem Today

There have been several other books about the dying patient in recent years. These have either been general reviews with little or no clinical material (7–13) or have included "normal" economically favored subjects (14, 15).

A large group of individuals, characterized by higher psychopathology and lower socioeconomic status, have not yet benefited from our increased interest and proficiency in the management of the dying patient, as Sudnow (16) has illustrated. He described the care of the terminally ill in a 440-bed county general hospital that treated mainly indigent patients, many of whom were black. The nature of the organization did not require assumption of any extended responsibility to particular patients and their families, as would normally be found in a private hospital. "... alcoholic patients ... [patients] from lower-class settings, prostitutes, suicidal cases, vagrants, narcotic addicts, and the like, when encountered in grave borderline illnesses, were normally accorded a more rapidly fatal fate. These patients were [viewed as] less interesting [and] less deserving" (16, p. 206).

In an earlier work, Shands (17) described a similar trend in the tumor clinic of the Massachusetts General Hospital, Boston, Mass. He found that many cancer patients dropped out because the traditional shifting of clinic staff led to frequent disappointment in their efforts to form a needed dependent relationship. Other reports

Dr. Levinson is Associate in Psychiatry, Mount Sinai School of Medicine of the City University of New York, Fifth Ave. and 100th St., New York, N.Y. 10029.

The author wishes to thank Lawrence Roose, M.D., for his helpful comments during the preparation of this paper.

have shown that the adequacy of case management decreases with sociocultural distance between the clinician and his patient (18).

FACTORS LEADING TO OBSTACLES IN TREATING DYING PATIENTS

A number of factors can lead to obstacles in the treatment of the dying patient by causing abnormal mood states, excessive regression, negativism, acting out, abuse of medication, and countertransference reactions on the part of the staff. I have found the following factors most likely to lead to complications in the treatment of the dying patient: 1) severe ego deficiencies in the areas of frustration tolerance, contact with reality, and cognitive function; 2) pathological coping mechanisms that lead to withdrawal, isolation, suspicion, and conflict with doctors, clergy, family, and hospital staff; 3) the nature and severity of the physical disease; 4) religious, socioeconomic, cultural, and racial barriers; 5) lack of cooperation by the family; 6) iatrogenic factors stemming from the physician's unresolved feelings about death and his frustrated omnipotence; and 7) shortcomings in the patterning of medical care. Chronic schizophrenia and mental subnormality, which were included under factor 1, accounted for 3 cases in my sample of 14 patients. Factor 2 was a steady feature in the borderline psychopathology that characterized most of the remaining subjects in the cases I observed. A discussion of borderline traits that present obstacles to treatment precedes case histories illustrating these factors.

Borderline Traits as Obstacles

While the number of psychotic patients in the general population is not large, the incidence of borderline individuals is considerable. In the population of dying patients there are also stable character disorders that have decompensated under the stress of mortal disease. The borderline patient who is terminally ill often shows an excessive use of denial, coupled with marked deficiencies in such ego functions as self-observation, reality assessment, perception, integration, and communication. There is a lack of tolerance for anxiety and other affects, making it impossible to go through a process of protest and mourning (19). These patients find it difficult to feel concern for their objects and to feel guilt. Their reactions take primitive forms of rage and impotence rather than mourning and regret over aggression. They tend to withdraw from too close an emotional involvement, which lends a shallowness to their lives.

Other characteristics associated with the borderline level of psychopathology are obsessive and compulsive mechanisms, hypochondriasis, paranoid trends, and schizoid traits. These elements often present overwhelming barriers to the establishment of the working relationship that is necessary to effectively help the dying patient. An obsessive borderline patient tends to intellectualize the experience of dying, to employ isolation to excess, and to regress into an ideational rather than relational world. A hypochondriacal patient may be preoccupied with symptoms rather than relationships and may even feel relief and a sense of vindication because his illness is a "real" disease.

The patient with paranoid character traits is likely to react to his progressive organic disease with heightened distrust and suspicion that is fed by growing anger, despair, frustration, and helplessness. The individual with a schizoid tendency reacts with increased withdrawal, seclusiveness, and fantasy preoccupation. These reactions present formidable obstacles to the physician who attempts to care for a dying patient during his terminal illness.

Patients who present a narcissistic personality structure often have functioned very well prior to their disease, despite an inordinate need to be admired, a shallow emotional life, and a tendency to exploit their objects. Under the stress of terminal illness, they feel extreme envy and despair, and their enhanced distrust and depreciation of others leaves them completely unable to depend on anyone. The ravages of disease often increase their underlying rage and lead to the appearance of paranoid traits that further impede the staff's efforts to help them.

Other borderline-type traits include the impulse neurosis—a form of character pathology that finds expression in alcoholism and drug addiction among the general population. Such patients' pursuit of drugs for terminal pain is particularly difficult to manage. This group of patients merges with the "acting-out" personality disorders, which present a particular proclivity for suicide. Finally, there is the passive-dependent personality, who is often lonely and pessimistic and manifests a deep sense of futility and hopelessness.

The following sections will describe patients I studied who presented obstacles related to the factors I have enumerated.

PATIENTS STUDIED

While engaged in psychiatric consultation in a large general hospital, I focused on referrals that presented obstacles in the management of the dying patient. These "more difficult" cases were selected from cancer patients referred from two services—ear, nose, and throat (ENT) and hematology. During a two-year period, I studied a total of 14 individuals—8 surgical and 6 medical cases. They represented only those consultees who had not accepted recommended psychotherapy but who could be partially followed anyway, or those who initially accepted contact but then broke it off on one or more occasions. In each case, the cancer was at least moderately advanced and the prognosis was poor. Eleven patients died within two to six months after referral. There were 9 men and 5 women, with an average age of 46. Every subject I studied was seen for at least six sessions and most patients had many more sessions. In addition, there were consultations with medical staff, social service, family, and clergy.

The ENT subjects were generally referred by the nurs-

UNIVERSITY COLLEGE OF MEDICINE LIBRARY

ing staff because they were not experiencing the level of feeling associated with fatal disease. They usually manifested stoicism or excessive depression. The hematologic referrals were usually made by the attending physician and were often associated with untoward emotional reactions to chemotherapy with such drugs as cortisone, cyclophosphamide (Cytoxan), and vincristine sulfate. The undue stress precipitated or underscored existing psychopathology.

There are significant differences that cannot be overlooked between the patients with progressive tumors (many of them treated surgically) of the ENT service and those with the intermittent, invisible cancers of the blood system (20). However, patients with these diseases share a common ground when it comes to coping with death.

Case Reports

In the first case I will describe, excessive use of denial and paranoid mechanisms formed a serious obstacle to treatment. The second case deals with a borderline patient with severe acting-out tendencies.

Case 1. A 61-year-old truck driver was dying of metastatic carcinoma in the neck region. Although he had had extensive surgery, the patient employed massive denial toward his fatal disease, and he displaced all feelings of concern onto a chronic shoulder ailment caused by neuralgia. His frustration, anger, and helplessness resulting from the progressive debilitation were projected onto physicians, whom he viewed as sadistic, negligent, and inadequate.

Another important obstacle in establishing a relationship with this patient stemmed from his pseudomasculine and anti-intellectual attitudes, which were related to his social class. He viewed emotional illness or even talking about feelings as a sign of weakness and as a cause for ostracism. Therefore, he presented overwhelming resistance to behavioral consultation, whether from a nurse, social worker, or physician. In addition, he was suspicious of all educated people and of any process that smacked of intellectualism. He employed total denial of a marked sense of intellectual, social, and economic inferiority and of fears of rejection and passivity. In his decline, he presented an ongoing and grandiose monologue of former physical strength, emotional stability, and vocational feats.

Case 2. A 29-year-old narcissistic and masochistic divorced housewife had leukemia for two years before she died. The disease, combined with her psychological immaturity, led to a series of emotional crises for which the internist insisted on psychiatric treatment. However, on each occasion she rejected the contact after a few sessions. Her object relationships had been consistently shallow and conflictual, and she had always maintained an infantile attitude toward her mother. These infantile needs were greatly intensified by her fatal disease and led to a period of promiscuity. Intense envy of others' health as well as rage at her mother, who had failed to protect her from the disease, led to much guilt and to an all-consuming sado-masochistic relationship with a lover. The therapist was an instant recipient of primitive transference wishes and of sadistic projections that made it difficult to alter the acting-out behavior. The patient's children suffered abuse and neglect as a result of her acting-out behavior.

In certain cases, religious, cultural, social, and racial factors can pose a formidable barrier in the treatment of the dying patient. Religion provides a harmonious means of coping with death for some people. Usually, religion emphasizes the importance of an afterlife, and it thus detracts from the finality of death and eases mourning and the need to withdraw the libidinal cathexes from love objects. Devoutly religious people often charge the image of God with libido that is freed in anticipation of entering a new world, and these individuals are often best served by the clergy. However, the dying patient who finds himself in the borderline area between religion and rationalism can provide formidable obstacles to therapy. Such patients can become skeptical of religious doctrine but at the same time view the therapist as too rationalistic, challenging, and threatening. Culture-bound patients often view the therapist as an outsider. Competition between agents of the different disciplines can develop.

Obstacles arising from racial differences can occur in such situations as treatment of a black patient by a white physician. In this situation, the physician becomes the recipient of a hostile transference based on the patient's too often real experiences of rejection and exploitation.

The third case illustrates a barrier to the treatment of the dying patient that resulted from cultural factors. A deficiency in the patterning of medical care was an additional obstruction in this case.

Case 3. A 20-year-old woman who had dropped out of high school and become involved with the counterculture was dying of Hodgkins' disease. She rejected psychiatric consultation in favor of a faith healer who was popular in the counterculture milieu. The patient terminated an important course of chemotherapy at the insistence of the faith healer. This proved to be an unfortunate choice, as the disease, which had carried a hopeful prognosis if given intensive treatment, returned after four months and led to rapid decline and death. The patient's weakened physical state limited subsequent psychiatric intervention, although her disillusionment with the faith healer made psychotherapy more acceptable to her. Guilt and anger in regard to the faith healer added further stress by increasing her depression and distrust, both of which posed additional obstacles in her treatment. The impasse was compounded when the patient was sent to a cancer hospital for her terminal phase in order to free a bed on an acute surgical ward. She was deprived of her familiar surroundings as a result of deficient medical care patterning and staff countertransference based on her earlier refusal to cooperate.

Lack of cooperation by family members can pose another important obstacle in the treatment of the dying patient. The impasse can be formidable, as the patient often finds himself very dependent on his family and deprived of his authority (if he has not already surrendered it). The final clinical example I will present illustrates the dramatic interplay of a combination of factors that can provide formidable obstacles to treatment. The two main elements in this case are the special nature of the organic process itself and iatrogenic factors.

Case 4. An attractive 24-year-old woman died of carcinoma of the maxillary sinus with extension to the eye and skull after a

one-year course of the disease that featured marked oscillations in the prognosis. The patient had been referred for psychiatric treatment because of the tragedy of "a beautiful girl having to lose her face," as noted by the nurses, who identified heavily with the patient.

Psychiatric treatment began after the first surgical procedure confirmed the diagnosis and the poor prognosis. The patient had a strong inclination toward denial but nevertheless began to express feelings of protest, anger, and despair in a brave effort to cope with her disease and arrive at a stage of acceptance. However, members of the medical staff revealed deep feelings of grief, helplessness, and guilt. They began to avoid the bedside on rounds and were not able to maintain an accurate prognostication in response to the patient's appeals. A second operation was scheduled and, although she was faced with mutilation, the patient revived denial, stopped coping with the inevitability of death, and discontinued psychotherapy. The operative procedure, which inflicted great suffering, involved the resection of large segments of the palate, maxilla, and orbit, as well as removal of the eye. The patient was left with great pain and was unable to eat due to the loss of the palate. She became malnourished and frail, and before she could get accustomed to the cumbersome oral prosthesis, the tumor had recurred.

The nature of the cancer that caused a young woman—heavily dependent on her looks for admiration, support, and relationships—to lose her face represented a special obstacle to treatment. As the true nature of her prognosis became only too clear to her again (after the reappearance of the tumor), the patient wanted to resume the psychiatric treatment, but she felt too ugly and ashamed. When I was finally admitted to the bedside, I immediately asked to see her unbandaged lesion and made sure not to flinch at the gruesome sight.

The patient began to drop denial and resume her confrontation with death. However, the medical staff could not be dissuaded from once again offering hope in the form of cryosurgery which they heavily rationalized. Denial was iatrogenically reinstated and by the time the patient recovered from the procedure, she was too weak to continue her efforts to arrive at an accommodation with death. She died with a feeling of hopelessness, futility, and distrust.

TREATMENT RECOMMENDATIONS

The approach to the more difficult dying patient consists of three parts: 1) dealing with the patient himself, 2) providing consultation for the personnel who care for the dying individual, and 3) influencing official attitudes and policies regarding death and dying.

Very limited goals must be accepted in the treatment of such patients. A good therapeutic relationship in the traditional sense cannot be expected. Instead, the therapist and staff often meet with distrust or apathy. The passive approach to therapy that may encourage ventilation in better integrated patients is viewed by these individuals with suspicion and seen as disinterest, condescension, foreboding, or pity. There is no time with the more difficult dying patient to work through borderline traits in the usual way. The therapist should quickly sense the patient's suspicions and insecurities and actively try to alleviate them.

Preoccupation with physical symptoms is another limiting factor. Support, reassurance, and relief of the physical symptoms for these patients takes precedence over communications related to death, separation, and loss. Flexibility is important. While confronting rigid defenses in one patient, the therapist should be agile in responding to more fluid and changing impulses, affects, and defenses in another. The therapist may need to attenuate denial, counter withdrawal and apathy, sanction dependency, encourage protest, and combat excess depression —all within a brief span of time. Pathological defenses usually must be supported rather than challenged, and respect for the borderline patient's need for distance must be maintained. Suicidal intent may appear at any time. The treatment should be supportive, directive, and educative rather than interpretive.

The therapist should be able to use psychopharmacologic agents and analgesics with skill and imagination. Phenothiazines can decrease paranoid and schizoid symtomatology and also reduce the amount of analgesic needed. Inordinate depression may warrant the use of antidepressant medication. The therapist must be familiar with cancer treatment agents, their side effects, and their expected efficacy. Variability in the course of the organic process is an important factor to consider (21). Concern over death and dying increases with the progression of the disease and quickly fades as symptoms diminish due to spontaneous remission or active treatment intervention.

It is particularly urgent that the psychiatrist establish rapport with the primary care physician when the dying patient is a more difficult case. This is necessary because they must coordinate what the patient is told about his fatal illness and be responsive to each other's suggestions about analgesia, palliation, etc. The psychiatrist should serve an educative function for the primary physicians who themselves must care for most dying patients. It should be demonstrated that the emotional needs of the dying can be responded to within reasonable amounts of time. This instruction can be given informally during daily rounds as well as through case presentations during grand rounds. Subtle departmental influences that quietly discourage a young house staff member from "sitting with" a dying patient should be uncovered. Discussion by the medical and nursing staffs of their feelings about death, as well as their attitudes toward "psychos" and socioeconomically and morally deprived individuals, can be valuable in modifying iatrogenic factors in the treatment of dying patients (22).

To influence official attitudes, efforts must be made to recognize the dying patient's special needs. Public funding should be sought for research and the development of varied programs. Then, each case could be carefully screened and a decision made as to whether psychiatric treatment was needed and, if so, what type of therapy should be given. At the same time, another decision would be made as to whether the patient was suitable for treatment on a general ward, a cancer ward, a terminal care hospital, or at home. Public and private health insurance should compensate physicians for the additional time required by the emotional needs of the dying, and the family should be covered for specific expenses from

caring for the patient at home during the terminal phase.

Finally, it is important to equip the medical student with the ability to recognize and respond to the emotional needs of the many terminally ill patients he will encounter. Along the same lines, continuing education programs for practicing physicians should promote the theory and practice of thanatology. All of these efforts should receive confirmation by the appearance of appropriate questions on licensure examinations, specialty board examinations, and during periodic review.

A Schizophreniform Behavioral Psychosis Mediated by Dopamine

BY DAVID L. GARVER, M.D., R. FRANCIS SCHLEMMER, JR., JAMES W. MAAS, M.D., AND JOHN M. DAVIS, M.D.

The authors conducted a study in which schizophrenic-like behavioral disturbances were induced in members of a macaque social colony by the chronic administration of d-amphetamine. Animals given the drug showed hypervigilance, hyperactivity, fragmented and repetitive behaviors, and progressive social withdrawal as well as the development of solitary stereotypies. The syndrome was dissected pharmacologically with alpha-methyl-para-tyrosine, chlorpromazine, pimozide, and haloperidol. Based on the behavioral findings and the known mechanisms of action of these drugs, the authors conclude that the major elements of the psychotic-like behavior induced by d-amphetamine were mediated by dopamine systems.

A SYNDROME VIRTUALLY INDISTINGUISHABLE from paranoid schizophrenia has resulted from street use or supervised administration of large quantities of amphetamines in amphetamine abusers who had no evidence of prepsychotic conditions (1, 2).

Similarly induced and similar appearing behavioral alterations in nonhuman primates could provide an animal model of psychosis from which much information could be gleaned concerning the function and interrelationships of critical neurotransmitter systems. Documentation of such psychotic behaviors may be possible through observation and quantitation of alterations in the rich variety of social interactions and individual behaviors induced by the administration of d-amphetamine to members of a nonhuman primate social group.

METHOD

Adult feral stumptail macaques with stabilized social relationships were observed in their colony at the same hour daily. Behavioral scoring encompassed both social and solitary measures. Each animal, in rotation, was scored during a 30-second interval with regard to 15 social and 13 solitary behaviors (there were 12 such intervals for each animal during each daily scoring period). Details of the scoring procedure appear in appendix 1. We will focus mainly on the following behaviors: activity —the number of intervals scored daily when movement other than checking occurred; stereotypies—the number of intervals when repetitive, often rhythmic behaviors (excluding checking or athetoid-like movements) that interrupted normal social or individual activities occurred; proximity—the number of intervals when the animal was less than three feet away from another animal; and checking—the total number of changes in eye direction or visual fields, with or without accompanying head movements, that occurred in 12 30-second intervals each day.

Four selected monkeys within the social colonies were given 2 mg/kg of d-amphetamine in time-release form (Dexedrine) every 12 hours via nasogastric tubing for a period of 3 to 20 days. Quantitation of behaviors was determined during the predrug period (baseline) and then again during the days when d-amphetamine was administered.

After a recovery period of at least 3 weeks from any previous study the same animals were pretreated via nasogastric tube with the following drugs immediately followed by the addition of d-amphetamine: 125 mg/kg of alpha-methyl-para-tyrosine (AMPT) every 12 hours for 14 days before d-amphetamine was given; 6.5 mg/kg of chlorpromazine (CPZ) a day for 36 days before addition of d-amphetamine; 0.5 mg/kg of pimozide (PZ) a day for 4 days before d-amphetamine addition; and 0.14 mg/kg of haloperidol a day for 21 days before addition of d-amphetamine with a stepwise increase in haloperidol to 0.57 mg/kg a day during days 17 to 20 of d-amphetamine administration. Finally, the animals again received two additional courses of 3 days of administration of d-amphetamine alone for comparison with earlier d-amphetamine-induced and drug-modified behaviors.

RESULTS

Syndrome Induced

Chronic administration of 2 mg/kg of d-amphetamine every 12 hours induced profound alterations in the behavior of members of the macaque social colony who received the drug. These animals manifested a state characterized by increased activity, frequent changes of visual field (checking), repetitive stereotyped behavior of a vari-

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Days 9–12	31.25 ± 6.00	14.50 ± 3.36	—	—

*The number of intervals during which activity and stereotypies were present daily and the total number of checks within each of the intervals were averaged for 4 days of baseline, days 1–4, days 5–8, and days 9–12 of d-amphetamine treatment and expressed as mean ± SEM for each animal.
**Days 1–3.

ety of types (stereotypies), and progressive social isolation.

Changes in activity. Periods of rest alternating with periods of activity characterize normal colony life for each of the animals studied. Administration of d-amphetamine interrupted this cycle by inducing a chronically active state. Animals receiving the drug would seldom be without movement, except for checking, for 30-second intervals. Table 1 shows the increase in intervals of activity for each of four animals given d-amphetamine.

Stereotypies. Each animal demonstrated d-amphetamine-induced stereotyped behaviors. These were manifest in a variety of forms: threatening, lipsmacking, social grooming, presenting, self-grooming, scratching, and rocking. Table 1 shows intervals of stereotyped behavior per 12 intervals observed daily for four animals, two of which were given the drug chronically for 4 days and two of which were given it for 12 days. When stereotyped behaviors are divided into social stereotypies and solitary stereotypies[1] it becomes evident that even when social stereotypies are present initially, solitary stereotypies eventually dominate during the course of chronic d-amphetamine administration. (See the figures given for Clancy in table 1.)

Checking. Among the most striking behaviors seen in the animals given d-amphetamine was the marked increase in checking (shifting of visual field). Although this phenomenon was more marked in some animals than in others, like stereotypies it appeared consistently in all animals treated with d-amphetamine. Table 1 shows the marked increase in checking from baseline levels, especially in Clancy. There was a gradual subsequent diminution of this behavior during days 5 to 8 and days 9 to 12.

Social isolation. Social isolation has already been demonstrated in the development of nonsocial stereotypies that replace usual interactions such as social grooming and other initiated social activities. In each animal social grooming was reduced during the first days and continued reduced throughout the course of d-amphetamine administration (12 days for Clancy and Freda, 5 days for Beckie and Suzie). Initiated social activity varied considerably during the first 3 days of d-amphetamine administration because of social stereotypies but was reduced beginning with administration day 4 until the end of d-amphetamine administration. Similarly, proximity scores varied early in this part of the study but showed rather consistent reduction beginning on day 5 until the end of d-amphetamine administration.

The reduction in social operations and the reduction in proximity scores during d-amphetamine treatment were as follows: Clancy showed only 5 percent of her baseline social grooming during days 1 to 3 and 5 to 12, 45 percent of her baseline-initiated social activity during days 5 to 12, and only 50 percent of her baseline proximity score during days 5 to 12; Freda showed 37 percent of her baseline social grooming during days 1 to 3 and 5 to 12, 39 percent of her baseline-initiated social activity during days 5 to 12, and 47 percent of her baseline proximity

[1]Rocking, a fragment of threat behavior, was considered a social stereotypy; this is further explained later in the paper under the heading "Discussion."

scores during days 5 to 12; Becky showed no social grooming during days 1 to 5 and 80 percent of her baseline-initiated social activity during days 4 and 5; and Suzie showed 32 percent of her baseline social grooming during days 1 to 5 and 35 percent of her baseline-initiated social activity during days 4 and 5.

Reproducibility

The basic elements of the d-amphetamine syndrome were found to be reproducible, but they were often less exaggerated when the same animal was reintroduced to the drug. Table 2 shows the means for activity, stereotypies, and checking for Clancy and Freda during two subsequent 3-day trials of d-amphetamine compared with these means at initial baseline and during the previous d-amphetamine administration.

Pharmacological Dissection

Alpha-methyl-para-tyrosine (AMPT). The means for the 3 final days of AMPT pretreatment, the first 3 days of combined AMPT and d-amphetamine, and the first 3 days of d-amphetamine alone on two separate subsequent occasions are shown in figure 1 for activity, checking, and stereotypies in two animals. The increase induced by d-amphetamine in each of the measurements was prevented or greatly diminished by pretreatment and concomitant treatment with AMPT.

Chlorpromazine (CPZ). Pretreatment and concomitant treatment with CPZ also prevented the d-amphetamine-induced behaviors that appeared during subsequent trials with d-amphetamine alone (see figure 1).

Pimozide (PZ). In contrast to AMPT and CPZ, pretreatment and concomitant treatment with PZ permitted d-amphetamine-induced elevation in checking. Like AMPT and CPZ, it inhibited d-amphetamine-induced elevation of activity and stereotypies (see figure 1).

Reversal of Broader Aspects of the Syndrome

After pretreatment with 0.14 mg/kg of haloperidol a day for 21 days, two animals were given d-amphetamine along with a gradual increase in haloperidol in an attempt to block the effects of d-amphetamine on both social and solitary behaviors. At low doses of haloperidol the characteristic d-amphetamine-induced syndrome appeared. Haloperidol was increased stepwise until days 17 to 20 of chronic d-amphetamine administration. At this time the dose of haloperidol was raised to 0.57 mg/kg a day and most of the behavioral measurements, both social and solitary, returned to or near baseline levels. Table 3 shows the "normalization" of the syndrome by haloperidol 17 to 20 days after initiation of d-amphetamine by comparing behavioral measurements during baseline, during both early and late periods of d-amphetamine administration alone, and during combined d-amphetamine and haloperidol administration late in the d-amphetamine period. d-Amphetamine-induced checking was not reversed by haloperidol.

TABLE 2
Reproducibility of d-Amphetamine-Induced Changes in Behavior of Two Macaques

Type of Behavior	Behavior Score Expressed as Means ± SEM*	
	Clancy	Freda
Activity		
Baseline	9.0 ± 0.5	8.7 ± 2.3
Initial d-amphetamine administration	11.7 ± 0.3	11.7 ± 0.3
Repeat d-amphetamine administration	11.7 ± 0.2	10.8 ± 0.9
Stereotypies		
Baseline	0.0 ± 0.0	0.0 ± 0.0
Initial d-amphetamine administration	12.0 ± 0.0	7.3 ± 2.6
Repeat d-amphetamine administration	3.5 ± 1.0	8.7 ± 1.2
Checking		
Baseline	12.3 ± 2.4	11.0 ± 1.6
Initial d-amphetamine administration	168.7 ± 31.3	37.7 ± 2.6
Repeat d-amphetamine administration	71.2 ± 15.8	54.0 ± 16.2

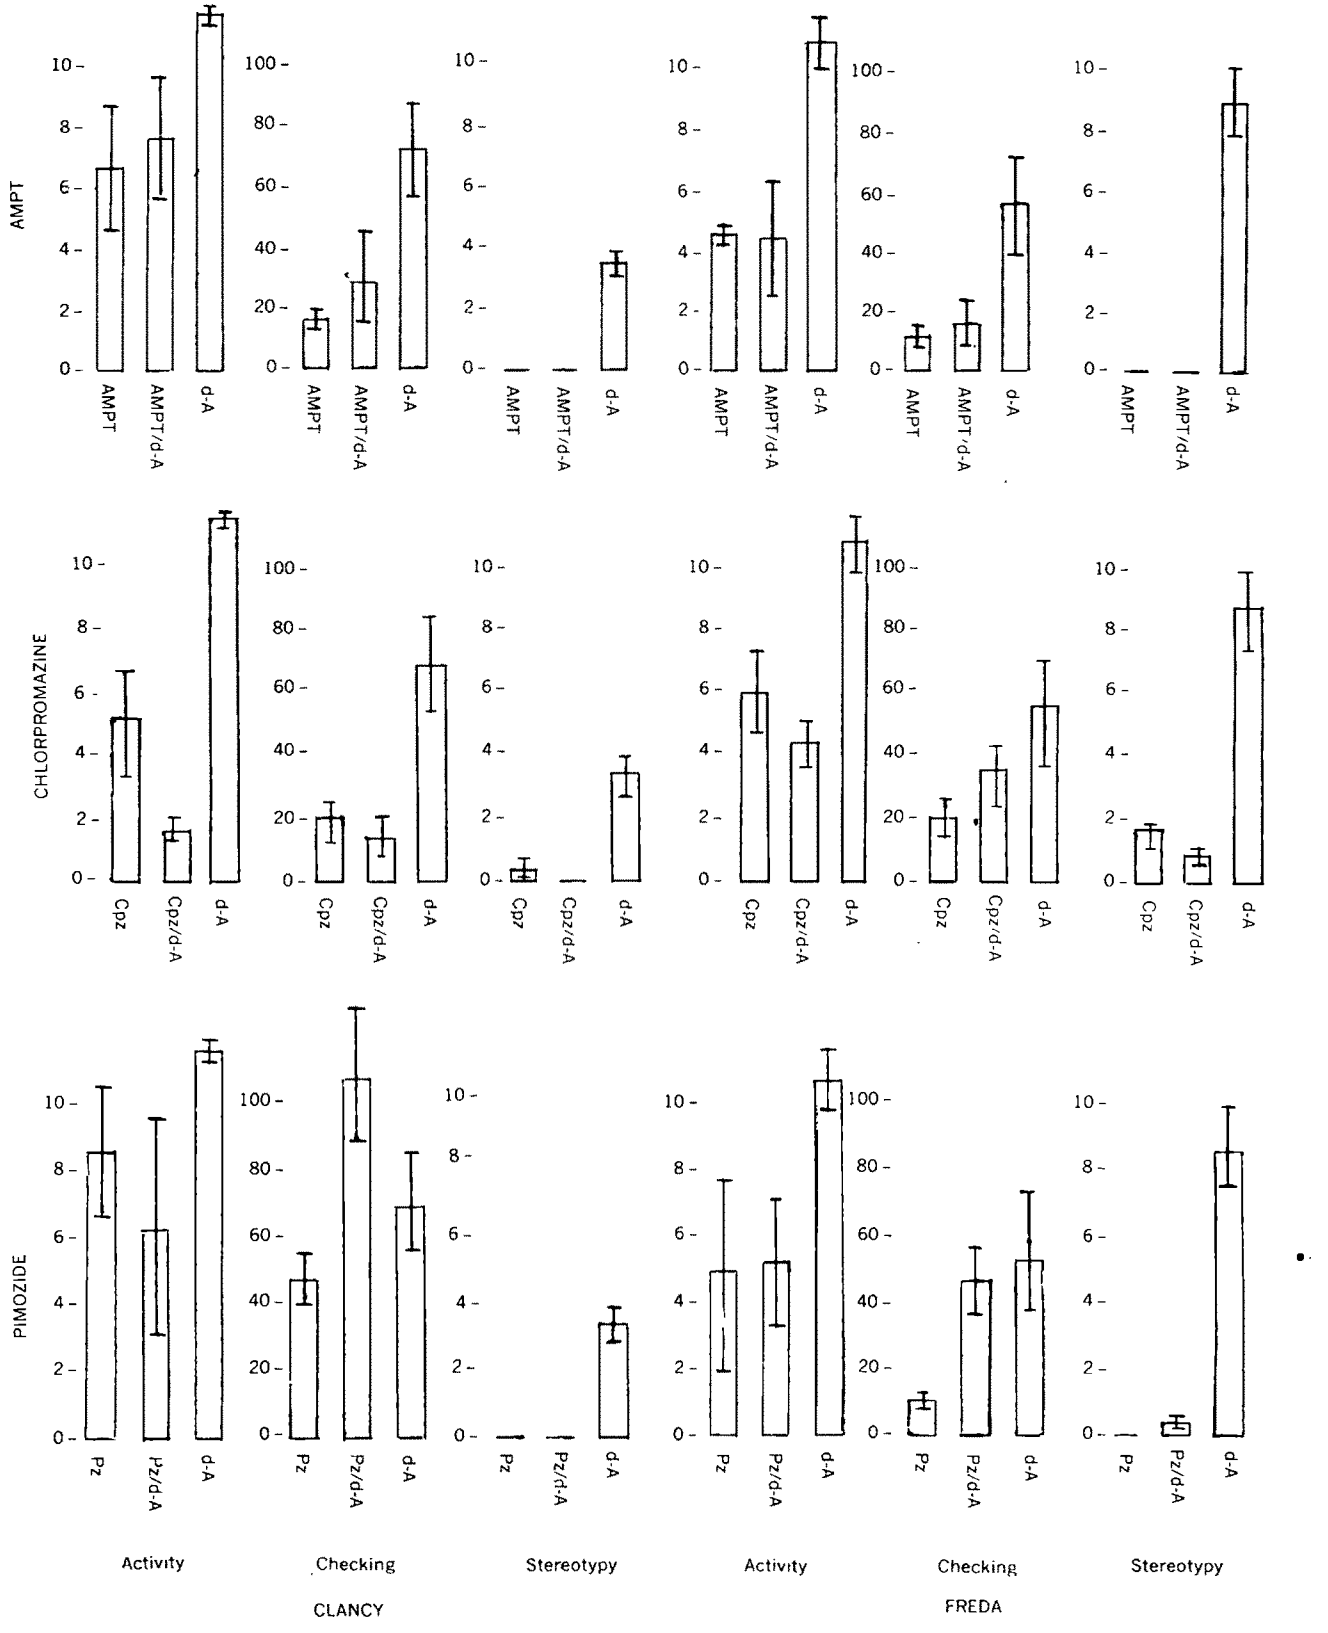
*These values show scores during the final 3 days of baseline, first 3 days of d-amphetamine administration, and the mean of the subsequent two trials with d-amphetamine alone on days 1–3 expressed as mean ± SEM for each 3-day period for each animal.

DISCUSSION

Interest in developing model psychoses displaying similarities to naturally occurring psychiatric syndromes has accelerated in the past several years (3–8). In this study we have documented the induction of psychotic-like behavior by chronic d-amphetamine administration. Our behavioral measurements (as well as demonstration films) give evidence of a frantically hyperactive and agitated state, with hypervigilance diminishing with the development of increasing social isolation and solitary stereotypies.

The attempt to move from qualitative and quantitative observations of behavior to generalizations concerning similarities of d-amphetamine-induced behavioral alterations in nonhuman primates and psychopathophysiology of the schizophrenias is fraught with difficulties. However, this effort must be made if a link is to be suggested between a state so induced in nonhuman primates and psychiatric illness.

Bleuler's Classification



Using Bleuler's four A's (autism, associations, affect, and ambivalence) (9), it is possible to group many of the d-amphetamine-induced or altered behaviors as possible manifestations of these states.

Autism is suggested by the progressive social isolation demonstrated by proximity scores, elevated levels of self-grooming as compared to social grooming, inability to attend another animal's social signals, and preoccupation with the performance of solitary stereotyped behaviors to the exclusion of normal social interactions.

Affective inappropriateness is suggested by the excessive threats that appeared in dominant animals when no discernible stimulus of implied threat arose from other animals. The inappropriateness of stereotyped threat-

*Mean Behavior Scores (±SEM) During Administration of d-Amphetamine (d-A) with Alpha-methyl-para-tyrosine (AMPT), Chlorpromazine (CPZ), and Pimozide (PZ) in Two Macaques**

*These values are for the following time periods: during the last 3 days on AMPT alone, first 3 days of concomitant AMPT and d-A, and the mean of two subsequent trials (days 1-3) of d-A alone; during comparable 3-day periods with CPZ and d-A; and during comparable 3-day periods with PZ and d-A.

TABLE 3
Comparison of Effects of d-Amphetamine Alone with d-Amphetamine and Haloperidol Combined on Behavior in Two Macaques

Type of Behavior	Behavior Scores Expressed as Means ± SEM*			
	Baseline	d-Amphetamine Alone		d-Amphetamine and Haloperidol
		Days 1–3	Days 9–12	
Reversed behavior				
Activity	8.4 ± 0.6	11.7 ± 0.3	12.0 ± 0.0	9.6 ± 0.9
Sterotypies	0.0 ± 0.0	9.7 ± 1.6	7.4 ± 1.4	0.0 ± 0.0
Social grooming	11.8 ± 2.1	5.7 ± 3.2	1.4 ± 1.3	15.1 ± 1.9
Initiated social activity	14.3 ± 2.4	63.8 ± 30.5	5.5 ± 1.8	16.8 ± 1.8
Proximity	9.8 ± 0.7	9.3 ± 1.1	5.5 ± 0.9	11.0 ± 0.6
Threatening	0.5 ± 0.4	45.7 ± 27.6	0.6 ± 0.47	0.8 ± 0.6
Self-grooming	1.5 ± 0.8	3.8 ± 2.0	9.6 ± 1.0	0.6 ± 0.3
Behavior not reversed				
Checking	13.0 ± 1.5	103.2 ± 31.0	22.9 ± 4.5	37.4 ± 11.2

*The values show the effects of the drugs during 4 days of baseline, 3 days early in d-amphetamine administration (days 1–3), 4 days later in d-amphetamine administration (days 9–12), and 4 days of combined d-amphetamine and haloperidol (0.57 mg/kg a day) late in d-amphetamine administration (days 17–20).

ening was apparent to the animals not given d-amphetamine. These animals failed to respond submissively, suggesting that the behavior of the animals given the drug may have lacked the appropriate affective tone for meaningful social intercourse.

Ambivalence may be demonstrated by threatening without a follow-through attack when the animal threatened does not respond with a submissive gesture. It is also suggested by the appearance of the further fragmented threat seen in stereotyped rocking. This behavior appeared only during the time of hypervigilance, soon after stereotyped threatening (forward rocking, eyes open, brow raised, ears back). We suggest that fragments of behavior patterns, in this case the beginning of a threat sequence, may also be a behavioral manifestation of ambivalence. Ambivalence was also suggested by the short-lived, interrupted social interactions such as grooming.

The presence of abnormalities of associations (formal thought disorder) cannot be documented in animals who have no spoken language. Yet patterns of behavior, a relatively consistent behavioral language, can be grasped by the experienced observer. A fragmentation of sequenced behavior, though difficult to quantitate, is experienced by the observer dysjunctively. Animals not given d-amphetamine infrequently approached and often actually distanced themselves from animals given the drug. This avoidance may have been the result of fragmented and unintelligible social cues. It is this fragmentation of previously patterned sequenced behavior, without apparent relationship to events, which may be a nonhuman primate behavioral counterpart to the unintelligible cognitive stream seen in schizophrenias clinically.

The focus of activity on the self (solitary stereotypies) rather than on outside events and relationships within the colony would appear to be correlated with relief from the hypervigilant state demonstrated by a reduction in checking. This "autistic" withdrawal might have been necessary for homeostasis in the animals given d-amphetamine and may have implications for clinical schizophrenias.

Dopamine-Mediated Theory of Psychosis

With the administration of AMPT, the d-amphetamine-induced changes in activity, checking, and the appearance of stereotypies were blocked, indicating that these elements of the syndrome are catecholaminergically mediated. Chlorpromazine also abolished the d-amphetamine-induced behaviors. In contrast, pimozide prevented the hyperactivity and stereotypies but not the hypervigilant (checking) state. Since AMPT inhibits tyrosine hydroxylase, chlorpromazine blocks dopamine and norepinephrine receptors, and pimozide blocks primarily dopamine receptors (10, 11), these data are consistent with the view that d-amphetamine induces hyperactivity and stereotypies by means of dopamine systems. It also appears that the hypervigilant state may be produced by effects on norepinephrine systems.

When we attempted to titrate haloperidol, a preferential dopamine receptor blocker (10), against the d-amphetamine-induced syndrome, we were able to achieve a remarkable "normalization" of both social and individual behaviors in the absence of fully reversing hypervigilance. This reversal of psychotic-like behaviors by haloperidol is consistent with the hypothesis that dopaminergic systems mediate the isolated, withdrawn, fragmented, and inappropriate behaviors (other than hypervigilance) induced by d-amphetamine.

A dopamine-mediated theory of psychosis or schizophrenia by no means requires that large quantities of dopamine are released from dopaminergic terminals and are present on or near dopamine receptors within the central nervous system. At least two other possibilities exist. One involves such supersensitivity of dopamine receptors that they are activated too frequently by normal or subnormal amounts of dopamine and are "normalized" by an antipsychotic drug (a dopamine-receptor blocking agent).

A second possibility involves a critical balance between

two or more neurotransmitter systems, one of which is dopamine. Anticholinergic agents alone have been described as producing motor behavior reminiscent of that seen after small doses of amphetamine (12). If there were a deficiency in acetylcholine or other critical neurotransmitter systems supplying critical areas of the central nervous system that are physiologically balanced by dopamine, critical balance could fall to dopamine predominance. This would elicit a dopamine-mediated psychotic syndrome without excessive dopamine being present at dopamine receptors, yet relieved by blocking with antipsychotic agents the activation of the dopamine receptor.

Investigations concerning neurotransmitter mediation in animal models of psychosis show promise for defining possible defects in neurotransmitter systems. Such definition would focus clinical research strategies and verify impressions gained clinically.

APPENDIX 1
Behavioral Scoring

Each animal in rotation was scored during a 30-second interval with regard to 15 social and 13 solitary behaviors, for a total of 12 such intervals for each animal during each daily scoring period. Social behaviors could receive additional scores when they took place with another animal during its 30-second scoring period (i.e., an approach by animal A to animal B during animal B's 30-second interval would be scored both for approach A to B and for being approached B by A).

An animal received a score for each occurrence of approaching, being approached, threatening, lipsmacking, withdrawing, scratching, or checking during a scored 30-second interval.

A single score was tabulated if social grooming, proximity, self-grooming, activity, or stereotypies occurred during a scored 30-second interval.

Scores were summed for each of the measurements for each animal for each daily scoring period. The initiated activity score is the sum of approaching, social presenting, submissive presenting, social exploration, social grooming, threatening, mounting, attacking, withdrawing, and lipsmacking for each daily scoring period.

Psychiatric Controversy: Man's Ethical Dimension

BY SILVANO ARIETI, M.D.

Although determinism may permeate human existence, man's moral values raise him above the level of an animal and enable him to direct his own life. The author suggests that psychiatrists should influence the patient to exert his will, make conscious choices, and, above all, assume a sense of responsibility for his own actions. In order to free the patient from whatever conditions hinder his will and to help him make choices, psychiatric treatment must consider man's ethical dimension.

COMMITTED AS WE ARE to the scientific method, we psychiatrists divide, dissect, and examine the psyche of the human being piece by piece. This is a legitimate procedure, provided that after the analysis we reach a synthesis, give the proper consideration to those aspects of the personality that could not expand, and, most important, do not leave out any basic human dimension.

We do not always follow this procedure. In our double allegiance to science and to man, who in his totality is not reducible to the accepted canons of science, we tend to adhere to traditional science exclusively and to minimize man's ethical dimension. In what I call the "ethical dimension" I include such vast areas as moral values and the phenomena of will, conscious choice, and responsibility.

I do not mean to suggest that the therapist should impose his values on the patient; I simply wish to stress that values always accompany and give a special psychological significance to facts and that when we deprive facts of their value, we fabricate artifacts which have no reality in human psychology. An individual may suspend his value judgment when he wants to examine a fact from a specific point of view, but then the ethical content has to be reestablished if the fact is to have human significance. If we remove the ethical dimension, we reduce man to a subhuman animal, an animal that is not *beyond* freedom and dignity, but whose organization *precedes* the experience of freedom and dignity—a subhuman animal to whom Skinnerian psychology can be safely applied.

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Dr. Arieti is Clinical Professor of Psychiatry, New York Medical College, New York, N.Y. Address reprint requests to him at 125 East 84th St., New York, N.Y. 10028.

It is easy for many of us who practice psychodynamic psychiatry to understand how Skinner's approach has only limited application to our work. The functions of the psyche that we study in our daily work—feelings, emotions, attitudes, introjection, guilt, expectation, purpose, goal, inner self, personality, determination, choice, will, etc.—are miraculous or imaginary entities for Skinner (1). According to Skinner, ideas, dreams, images, insights, and conflicts cannot be seen or observed and, therefore, do not count, nor can the existence of an inner life be inferred from them. Skinner follows a procedure antithetical to the medical procedure, for a physician does not simply observe his patient's behavior but also makes inquiries about what goes on inside of the patient.

Although I have never gathered statistics on a large scale on this subject, I am inclined to believe that many psychiatrists are ready to reject Skinner's position. But unfortunately, many of us are willing to accept other positions that do not consider adequately the ethical dimension. In contrast to the position of Rollo May (2), Leon Salzman (3), Leslie Farber (4), myself (5), and many others, a large group of psychiatrists and psychologists do not believe that there is such a thing as human will. Certainly a normal voluntary action consists of many steps, some of which are not yet susceptible to scientific analysis. We do not know when neurology ends and psychology begins. We do not know the intimate neurological mechanism that initiates a voluntary movement. Perhaps what we call will is the synthesis or result of many neuropsychological mechanisms plus newly emerging elements that in a tentative way we call autonomy, individuality, originality, creativity, and indeterminacy.

PREEMINENCE OF DETERMINISM

Determinism reigned supreme in the era of hard-to-imagine proportions that extended from the appearance of the atom to the development of the human cortex. The simplest entities (the subatomic particles) and the highest (some parts of the human cortex), respectively, opened and closed this vast era that unfolded over billions and billions of years. The most complex entity in our universe, the human cortex, again permits a certain independence from causality as it existed at the subatomic level studied by Heisenberg. However, the freedom of man,

made possible by his cortex, is different from the so-called freedom of the subatomic particles. It is integrated with the essence of man. Although this freedom produces an interruption in the deterministic chain of causes and effects, it immediately rejoins determinism, thereby re-establishing continuity, for the will of man becomes a *cause* of action. It is a causality compatible with free will. It is for future research to establish whether subatomic "freedom" becomes incorporated in some particles of neurons and changes ideas into free actions and thus reintegrates itself into the essence of man.

For many psychiatrists, including myself, what we call will, that ability by virtue of which we conform our behavior to our determination, is the culmination of the psychological functions of the human being. Certainly we can bypass our will. We may meekly obey others, or we may behave in conformity with our conditioned reflexes. If we have some psychiatric disorder, our will is hindered in various ways. If we are hysterical, we lose control of some functions of our body. If we are phobic, the avoidance of the dreaded event rather than our determination will guide our actions. If we are obsessive-compulsive, we feel obligated to obey internal injunctions even when they seem absurd. If we are psychopathic, we cannot say no to ourselves; we are under the impulse to satisfy our urges immediately. If we are catatonic, we go through a stage in which even our smallest movement may be endowed with cosmic responsibility and guilt; consequently, we do not move at all. Those of us who have intensely studied the catatonic type of schizophrenia consider the catatonic state to be the nadir of the human condition (6). Although the catatonic is not physiologically paralyzed, he cannot respond to people who touch him, bump into him, smile at him, or caress him. He appears to be a statue, but unlike a statue he hurts in a most atrocious way, having lost the most precious and human of his possessions —his will. By studying cases of catatonic schizophrenia of different degrees of severity, we can learn a great deal about the existence, unfolding, and impairment of the will (6).

Psychiatric treatment attempts to liberate the patient from whatever condition limits his will, whether it is a mild neurosis or a severe catatonia. It should be understood, however, that total freedom and total self-causation are not available to any man. Even partial freedom is not something a human being is born with; it is a striving, a purpose—something to be attained. Being born free is a legal concept that, although valid in daily life, has philosophical limitations. Striving for freedom is an unceasing attempt to overcome the conditions of physicochemistry, biology, psychology, and society that affect human life. The psychiatric patient has the additional burden of overcoming the conditions of his psychopathology, and the purpose of psychiatric treatment is to help him do so. It would be unrealistic to forget, however, that this self-causation is only a thin margin of a totality in which the majority of facts and events are ruled deterministically. But I feel that this thin margin is sufficient to change the world, to make history, to cause the rise or fall of man (5).

FREUDIAN VIEW OF THE CONCEPT OF WILL

Classical Freudian psychoanalysis has a controversial (and I would say ambivalent) attitude toward the concept of will. On one side, Freudian psychoanalysis adheres to a strict deterministic view of reality and life that leaves no room for human choice. According to Freud, most of our actions are caused by unconscious motivation, and as long as our actions are the result of unconscious motivations, we cannot call ourselves free or feel responsible for what we do.

Like many other great thinkers, Freud contradicted himself on many issues, including the question of will. More than any of his predecessors or contemporaries he revealed the role of the unconscious wish as a determinant of human behavior. But Freud's great discovery does not imply that will has no role. Let us consider Freud's famous statement, "Where id was, ego must be." Freud meant that as a result of psychoanalysis, unconscious wishes, generally relegated to the id, must become part of the ego; i.e., they must become conscious. But what is the purpose of this? To make the id part of the ego does not mean unleashing the unconscious wishes or giving them free reign or unrestricted access to conscious behavior, although this is the way some people interpret Freud's statement. I believe that Freud meant that once the unconscious wishes become conscious, they will be regulated by the functions of the ego. The individual will be in a better position to accept or reject them. In other words, Freud conceived psychoanalysis not as a liberation of the id but as a liberation of the ego from the unwanted, unconsciously determined oppression exerted by the id. Thus, psychoanalysis has the function not of restricting but of enlarging the sphere of influence of the will. Its aim is to return a sense of responsibility to the human being for many actions that previously were beyond his control. In this respect, psychoanalysis enlarges the ethical dimension.

POSITION OF SOME PSYCHODYNAMIC SCHOOLS

In addition to Freudian psychoanalysis, some schools of psychodynamic psychiatry have also neglected the role of autonomy and individuality, which are prerequisites for free will. Whereas some geneticists believe that most or all of our life is predetermined by our genetic code, some psychodynamic psychiatrists believe that our present life is entirely determined by our past experiences—by what our parents, families, schools, and society have done to us. Thus, although the psychiatrists who focus only on the environment do not invoke heredity, their basic philosophy is similar to that of the geneticists: man's destiny is shaped by forces external to the self.

WE CREATE OUR OWN SELF-IMAGE

Obviously we are influenced by external forces. Genetic, familial, and social factors are important, but not to the extreme degree that many psychiatric studies im-

ply. Conceptions that view the individual only as a passive agent or tabula rasa, as a receiver, or as a puppet pulled by strings of different kinds have prevailed in daily psychiatric practice. For instance, when we elicit a history from the patient's family or (in most cases) from the patient himself, our aim is to establish how this history has made the patient what he is now. Some psychiatrists ignore completely the fact that the patient has always recreated that history. What he tells us is seldom what happened but more frequently what he perceived and interpreted, what he assimilated, and what his memory has constantly changed and given different meaning to. The child does not just reflect or absorb from the environment; he also tries to select what to absorb or what to give prominence to. The image that the child has of himself does not consist of reflected appraisals from parents or family members but of what the child did with those appraisals. In the same way, the image that he has of his parents and siblings, although related to the actual essences of these people, is not a mirror reproduction but rather a subjective interpretation. There is a definite discrepancy between the way reality and the significant people in one's life were in the past and the way one has perceived them. This discrepancy is particularly pronounced in the schizophrenic and preschizophrenic individual but also exists (to a lesser degree) in the neurotic individual and in all of us. This discrepancy is one manifestation of individuality. The image that the individual has of himself is particularly important because it is a major constituent of inner life or what is at times called the self. And, our self-image is not created exclusively by others but also by ourselves. We are among our own creative forces.

I must stress again that I do not mean that we are completely free. The self in whose creation we have cooperated is also the result of our specific biological endowment and a random mixture of external factors. The psychiatric patient has less possibility of contributing to the creation of his own self than the normal person because he was handicapped by external contingencies. However, the patient who has successfully progressed to an advanced stage of treatment will stop blaming his mother or father, his childhood, his spouse, or the conditions at work for all his troubles. The more he becomes conscious of his secret life (the more he understands his thoughts and motivation), the more he increases the area of his responsibility. He recognizes the role that other people played in his life, but he assumes some responsibility for what happened to him and especially for the way he will direct his life in the future. Of course, it would be absurd for him to think that his destiny will be entirely in his own hands, but he is aware that he too is a determining force in his own life.

Insofar as psychiatric treatment increases the ability to make choices, it is constantly involved with man's ethical dimension. Any choice that affects others reveals our sense of responsibility, our concern or lack thereof not only for ourselves but for others. What we are responsible for is typically a product of our own self. Of course, when responsibility becomes one's only concern, it is distorted and assumes a tyrannical role; however, its absence, or a great decrease in it, produces in us the psychopathic variety of human life.

SELF-REALIZATION AND THE ROLE OF PSYCHIATRIC TREATMENT

A misinterpretation and a misapplication of some psychiatric and psychoanalytic concepts stand out among the many causes of the permissiveness and hedonism of our days. I refer particularly to the concept of self-realization that has persuaded many to strive for self-fulfillment, even if this means disregarding the rights of others. This misunderstanding derives not only from the already mentioned concept of id liberation, misconstrued from Freudian theory, but also from a broad generalization of some concepts of the neo-Freudian schools of psychoanalysis and humanistic psychology. Maslow, Horney, and Fromm believe that the highest ethic, as well as the aim of psychotherapy, is the one that leads to self-realization.

This point of view is controversial on many grounds. First, there is no preordained, specifiable potential in man that has to be realized. Man is indefinite and capable of unpredictable growth because of the multitude of possible encounters with different systems of symbols and concepts (7). Man must aim at continuous growth or self-expansion, but not at a mythical realization of an assumed potential. Man is not an acorn that may become an oak. For man, there is no question of potentiality but of infinite possibilities. Second, "self-realization" is very deceptive as a subjective experience. Reading the writings of Mussolini and Hitler, and even of some politicians of our own times, one is forced to conclude that these people were sure of realizing themselves and their "own destiny" by following a mission or mandate given them by the people. Third, and most important, self-realization ignores the actual problem of ethics, one's moral relation to others. Self-fulfillment is not necessarily an ethical aim; it may be a form of hedonism and narcissism, again easily recognized in the lives of some politicians. What some authors mean by self-fulfillment is a legitimate aspiration. However, when self-fulfillment is pursued, it is not on ethical grounds but for personal gratification. To remain ethically justifiable, it must not interfere with ethical principles. We certainly should aspire to our psychological growth and happiness, provided we do not infringe upon the rights of others.

Ultimately, we must ask the question of whether psychiatric treatment itself conditions the patient by making him choose accepted behavior and reject what is considered socially unacceptable behavior. To the extent that treatment has this effect, it is not psychodynamic; it does not enlarge the freedom of man. We must be able to make a fine distinction. Influencing the patient (as psychodynamic treatment does) does not mean conditioning the patient; it means increasing the patient's vistas and his range of choices. The patient then does the

choosing. As a matter of fact, as Halleck (8) has recently stated, the patient should have a voice even in the choice of his own treatment.

CONCLUSIONS

Often a defeatist philosophy of life, in which everything is presumed to be fallacious or illusionary, permeates psychotherapy. According to this view there is no escape from the determinism that regulates human life (9); human life is a part of a deterministic cosmos in which everything is caused by something else. Obviously a large part of our existence is determined by outside forces. Certainly we must agree with Freud that the part of the iceberg which is submerged is much larger than that above the surface. But from that part which is above water we can see the polar star and a large part of the firmament. Even though the deterministic forces prevail and ultimately overcome us, we should not feel defeated if we have added our will, our choice, and our sense of responsibility to the conditions that give meaning and direction to our existence.

Private Psychiatry and Accountability: A Response to the APA Task Force Report on Private Practice

BY STEVEN S. SHARFSTEIN, M.D., M.P.A., CARL A. TAUBE, AND IRVING D. GOLDBERG, M.P.H.

The authors note that the imminence of national health insurance makes it very important to determine the roles, efficiency, and effectiveness of both the private and the public sectors of mental health care. The difficulties in distinguishing public from private care are examined. The authors present estimated distributions of care by type of provider that differ from those of an APA task force report on private practice. They point out the need for objective research on the quality of care in both sectors and on the effectiveness of alternative mental health systems, suggesting that public choices should be made on the basis of correct interpretations of reliable data and accountability to those being served.

AS NATIONAL HEALTH INSURANCE coverage for mental illness is debated in the coming months, one of the issues will be the role private psychiatry will play in the final plan. The future and structure of mental health services in this country will hinge on the benefit package provided by the plan. A balanced assessment of the current contribution of private practitioners is necessary in order for the public to be served with quality care at reasonable cost.

The American Psychiatric Association's task force report, *The Present and Future Importance of Patterns of Private Psychiatric Practice in the Delivery of Mental Health Services* (1), is one attempt to assess "the vital role of its private practitioner members in the delivery of mental health services to the American people" (p. v). The report makes several statements regarding the superiority of the private practice delivery system, including the following:

> It seems doubtful that there is any health service rendered by a public facility that could not be as, or more, effectively rendered by the private sector of psychiatry from the standpoint of quality and economy. . . . To the extent public facilities can integrate the private sector of psychiatry under contractual or fee-for-service arrangements, the public will be better served and at the same or possibly a lower cost. (pp. 20, 21)

These conclusions have elicited comments that challenge the quality and economy of organized patterns of care and public policies favoring organized care settings such as community mental health centers (2).

In this paper we will take issue with some of the task force's data and their interpretations of the data. We will also deal with issues related to the distinction between public and private care and to accountability, quality assessment, and economic factors. These issues are necessary components in any comparative analysis of the organization of mental health delivery systems, and they must be faced before public policy regarding national health insurance can proceed in a rational and responsible manner.

DATA ON THE RELATIVE ROLE OF THE PRIVATE SECTOR

The task force report presents an analysis of the contributions of psychiatrists in private practice to the delivery of mental health services. Their analysis was based on a study that was conducted in the state of Kentucky in 1970 (3). From these data, the report concludes that

> The private practice segment of the profession in Kentucky is the largest component of the state's mental health delivery system. This finding quite possibly may be applicable to the nation as a whole. (1, p. 15)

The report later states with more certainty,

> All in all, it seems fair to estimate, as the Kentucky survey suggests, that roughly half of about 5,000,000 persons who seek, each year, psychiatric care in the United States seek and receive it from private practitioners. (1, p. 19)

Finally, near the end of the report, all uncertainty about the relative role of the private practitioner seems to have disappeared, and we find the statement,

> It is useful to picture the private practice sector of psychiatry as a massive national outpatient and inpatient service for the mentally ill, and one that meets the service needs of about half of all emotionally disturbed persons who seek professional help. (1, p. 27)

The authors are with the National Institute of Mental Health, Alcohol, Drug Abuse, and Mental Health Administration, 5600 Fishers Lane, Rockville, Md. 20852. Dr. Sharfstein is Chief, Evaluation Branch, Office of Program Development and Analysis. Mr. Taube and Mr. Goldberg are with the Biometry Division, where Mr. Taube is Chief, Survey and Reports Section, and Mr. Goldberg is Chief, Evaluation Studies Section. Address reprint requests to Dr. Sharfstein.

Views expressed herein are those of the authors and do not necessarily reflect the opinions, official policies, or positions of NIMH or the Alcohol, Drug Abuse, and Mental Health Administration.

Aside from the statistical hazards inherent in projecting findings from a single state to the nation as a whole, other data on the mental health system that were not examined in the report seem to indicate that more modest claims regarding the role of the private practice sector of psychiatry might be more appropriate, even in the state of Kentucky. An examination of some of these data follows.

Kentucky Data

The most recent year for which the Kentucky Department of Mental Health has published data is 1972; these data relate to state mental hospitals and community mental health centers (4). In order to compare these figures with those for private practice, we will accept for the moment the 1970 survey (3) estimate of 12,300 individuals under the care of private practitioners in Kentucky and assume for the purposes of illustration that this number increased by 25 percent between 1970 and 1972 (to 15,375). This provides us with the following picture: Of the total number of individuals under psychiatric care in Kentucky in 1972 (N=66,254), 23 percent (N=15,375) were served by private practitioners, 12 percent (N=7,948) by state mental hospitals, and 65 percent (N=42,921) by community mental health centers (CMHCs).

These data seem to indicate that private practice accounts for a quarter—not a half, as stated in the task force report—of the individuals served annually. This proportion is more consistent with the results of a study by Hornstra and Udell (5), who found (in a seven-county area which included Kansas City, Mo.) that 29 percent of all individuals applying for psychiatric services during a one-year period (1967–1968) were accounted for by the private sector and that 35 percent of all those under psychiatric care on a given day were accounted for by private psychiatrists. Also of interest in this regard are unpublished data from the psychiatric case register in Monroe County, N.Y. (6), which indicate that of all persons seen in psychiatric settings in that county in 1971, fewer than 20 percent were seen by psychiatrists in private office practice (even after adjustment for underreporting to the register), and about a third of those seen by the private practitioner were also seen in other psychiatric settings during that year.

National Estimates

Discussion of task force estimates. The task force calculates the number of persons served annually by private psychiatrists in the United States in the following manner:

1. According to a study by the American Medical Association (7), an average practitioner in psychiatry has 55 patient visits a week and works an average of 48 weeks a year (1, p. 16).

2. These figures were multiplied by an unreferenced figure of 8,000 psychiatrists in full-time private practice (8,000 × 48 × 55), yielding a figure of 21,120,000 visits annually to private psychiatrists (1, pp. 3, 18).

3. An unreferenced figure of 300 was used as the number of individuals seen annually per psychiatrist, which, multiplied by the number of psychiatrists (8,000), yields a figure of 2,400,000 individuals seen yearly by psychiatrists in private practice (1, p. 18).

We arrived at an estimated national distribution using the task force's figures and unpublished estimates of individuals seen in public and private facilities that we derived from National Institute of Mental Health (NIMH) data (8), adjusted for duplication.[1] Of a total of 5,753,000 persons receiving psychiatric care in 1971, 42 percent (N=2,400,000) were seen in private practice, 17 percent (N=972,000) in private facilities, and 41 percent (N=2,381,000) in public facilities. (These data are unduplicated within settings only.)

There are several factors that must be considered in interpreting these data. First, the counts for the private sector are not completely unduplicated. A certain proportion of the episodes in the private-practice category represent people who were admitted, during the course of their episode with the private psychiatrist, to a private mental health facility (e.g., private general hospital or private psychiatric hospital). Such people would also be counted among the episodes in private facilities, which inflates the total count of individuals in the private sector.[2]

A second problem concerns the validity of the task force estimate of 2.4 million persons under the care of psychiatrists in private practice. A critical issue in this estimate is the task force's figure of 300 different individuals under care annually per private psychiatrist.[3] Data from various surveys of psychiatrists that were not cited by the task force seem to indicate that 300 is a considerable overestimate (see table 1).

Modified national estimates. A rough estimate of the number of different patients seen annually by private psychiatrists may be obtained from the unweighted average of the results of the surveys summarized in table 1. If one rejects the data from California (15), where the practice of psychiatry is particularly atypical of the nation as a

[1]Facility data on episodes (i.e., the number of people under care at the beginning of a year plus all admission actions during that year) were converted to "individuals" by multiplying the episodes by 0.8, a factor derived from the Maryland Psychiatric Case Register, which indicated that persons in that register had an average of 1.2 episodes of care per year.

[2]An estimate of this overlap is provided by an NIMH study of discharges from general hospital psychiatric units (9) that indicated that 54 percent of the discharges from private general hospital psychiatric units were referred to a private psychiatrist. In addition, another study of private mental hospitals (10) indicated that the referral source to the hospital was a private psychiatrist in 45 percent of the cases. Using these proportions, it may be estimated that 216,000 of the 972,000 estimated episodes for private facilities were referred to or from a private psychiatrist. This number should be subtracted from the total of 3,372,000 persons listed for the private sector (private facilities plus private practitioners). The degree of overlap between the public and private sectors in patients treated is unknown, but probably small, and is therefore ignored for purposes of this discussion.

[3]One might also take issue with other estimates used or quoted in the report. For example, the report notes that the AMA study (7) referred to by the task force reported that the average number of hours spent weekly by psychiatrists in providing direct care was 37.3. An APA study (11), however, reported this average to be 31.5 hours—a substantial discrepancy.

TABLE 1
Number of Different Persons Seen Annually per Psychiatrist: Selected Surveys

Authors	Year Covered by Survey	Site	Number of Different Patients Seen per Year
Schulberg (12)	1963	Massachusetts	135
Bahn and associates (13)	1963–1964	United States	107
Klee and Warthen (14)	1965	Maryland	93*
Littlestone and Brown (15)	1966	California	259**

*The median was 32 for psychoanalysts. The figure for nonanalysts is used because it is more representative of private practice in general.
**Estimated from other data given in the study.

whole, the average is 112 individuals seen annually per psychiatrist. (If the California data are included, the average is 149—still only half the figure used in the task force report.) Using this average of 112 and eliminating the overlap of an estimated 216,000 patients seen in both private facilities and private office practice, the unduplicated count of persons seen in the public and private sectors may be estimated as follows: Of a total of 4,033,000 psychiatric patients in 1971, 41 percent (N=1,652,000) were seen in the private sector, and 59 percent (N=2,381,000) were seen in the public sector. (These figures are unduplicated within sector.)

However, this method of estimating the role of the private sector in the provision of mental health services is deficient because it does not take into account the volume and kinds of services given to each person. Table 2 presents the units of service generated annually by the public versus the private sector of psychiatry, based on unpublished NIMH data for 1971. Because inpatient and outpatient services are so different, they are treated separately. (Units of service in table 2 are allocated to the public or private sector according to the ownership of the facility.)

The task force estimated that private psychiatrists generate 21,120,000 visits annually. Presumably, this includes the estimated 6,210,000 visits in private mental health facilities shown in table 2. Private office practice visits exclusive of these visits would number 14,910,000. This estimate is almost three and a half times the figure given by the National Center for Health Statistics (NCHS), based on a national sample survey (16). Even if one assumes that the NCHS survey represents an underestimate of 50 percent (resulting from hesitancy about reporting psychiatric care in a household interview), the modified estimate would be only 6,560,000, as contrasted to the task force estimate of 14,910,000. If we use the modified NCHS estimate of office visits (rather than the task force estimate) and the other estimates for outpatient and inpatient services shown in table 2, we derive the volume of services for the private and public sectors that is summarized in table 3. We find, therefore, that when the volume of services is taken into account, the private sector accounts for a total of 53 percent of outpatient visits and 12 percent of inpatient days.

TABLE 2
Estimated Annual Volume of Inpatient and Outpatient Services in Public and Private Psychiatric Facilities for 1971

Type of Facility	Inpatient Days (in thousands)	Outpatient Visits (in thousands)
Public		
State and county mental hospitals	95,584	2,171
VA psychiatric hospitals	11,945	1,182
General hospital psychiatric units	2,178	1,219
Federally funded CMHCs	2,225	3,376
Outpatient clinics		3,206
Total	111,932	11,154
Percent	88%	64%
Private		
Mental hospitals	4,293	506
Residential treatment centers for emotionally disturbed children	6,378	—
General hospital psychiatric units	4,794	1,661
Outpatient clinics	—	4,043
Total	15,465	6,210
Percent	12%	36%

TABLE 3
Estimated Annual Volume of Inpatient and Outpatient Services in Public and Private Psychiatric Settings for 1971

Type of Setting	Inpatient Days		Outpatient Visits	
	Number (in thousands)	Percent	Number (in thousands)	Percent
Private office practice	—	—	6,560*	27
Private facilities	15,465	12	6,210	26
Public facilities	111,932	88	11,154	47
Total	127,397	100	23,924	100

*Private office practice visits are based on modified NCHS data (16) rather than the estimate used in the APA task force report (1).

The question remains as to how these different units of service should be combined to arrive at a weighted total. A reasonable approach would be to use a weighting based on the cost of a visit in relation to the cost of an inpatient day, which is analogous to the American Hospital Association's model for combining outpatient and inpatient services to arrive at "adjusted patient days" (17). On this basis, using the ratio of allowable benefits under the Blue Cross and Blue Shield health insurance program for federal employees, we may assume that three outpatient visits are equivalent to one inpatient day. Thus, dividing the outpatient visits by 3 and adding this to the number of inpatient days, we arrive at a weighted measure of service units. The public sector accounts for 85 percent (N=115,650,000) of these units and the private sector for 15 percent (N=19,722,000).

Need for more and different data. The vast difference in the relative role of private psychiatry, when put in terms of the volume of services as opposed to the number of different individuals seen, is readily apparent from these data. Examining the kinds of services provided by the public and private sectors is also important in evaluating their relative roles. For example, Miles and associates (18) found that 44 percent of the individuals seen by private psychiatrists were seen only for diagnosis.

Data are also lacking on the relative efficiencies and effectiveness of different mental health professionals. Social workers, clinical psychologists, psychiatric nurses, and others provide valuable services. Like psychiatrists, these professionals practice in a mix of public and private organized care settings and in private offices. The difficulties in measuring their roles relative to each other and to psychiatrists complicate the issue still further.

PRIVATE VERSUS PUBLIC CARE: FURTHER ISSUES

Distinguishing Between the Two Sectors

The distinction between private practice and public care is not as clear as the task force report implies. The loci and organization of psychiatric care are varied, and there is a complex mixture of public and private funding involved. Direct public support, third-party payments (including Medicare and Medicaid), and out-of-pocket funds all finance different costs of both public and private facilities.

Like psychiatric facilities, professional providers are not easily distinguished as public or private, since they often work in different care settings. Psychiatrists do not fall into mutually exclusive categories of those who are salaried and employed in organized psychiatric facilities, either public or private, and those who are engaged in private office practice. While certain psychiatrists do fall into only one or the other of these two groups, many others are both employed in a public organized setting and engaged in private practice. Furthermore, many psychiatrists who are not employed in an organized psychiatric setting use such settings for their patients' care through their staff privileges at a hospital or other facility.

The available national data are either utilization data on mental health facilities or data on the activities of psychiatrists as a group. Neither of these data sets enables one to clearly distinguish the boundaries of the private sector. For example, if a psychiatrist sees a patient in his private practice, admits the patient to the psychiatric unit of a city or county hospital, and continues to see the patient on an outpatient basis after his discharge from the hospital, should this patient's hospital stay be counted as private or public care? NIMH data on discharges from city or county general hospital psychiatric inpatient units (8–10) include such patients in the public category.

The task force estimates that private psychiatrists see over 2 million different individuals a year. It neglected to point out, however, that a certain proportion of these psychiatrists are salaried employees in public organized mental health settings and that their patients are therefore treated in the public care system.

The task force report does describe several private organized care systems (e.g., health maintenance organizations and group practices) as distinct from solo private practice. This distinction is a more useful one than a private/public dichotomy, as it separates different models of mental health care delivery. The efficacy and efficiency of solo versus group or organized care is not spelled out in the report and, despite the proper delineation of several of these organized care systems as private, one is left with the impression that the task force equated private practice with solo practice.

Accountability, Efficiency, and Costs

The most essential issues we must deal with involve the accountability and efficiency of private psychiatry. Accountability to the public for medical care is an increasingly significant issue as national health insurance becomes an imminent reality. It is not enough to say that higher quality and lower cost care can be delivered by a particular sector of the mental health service system. One must specify what populations are under care among the range of mental health problems. Will the professional providers agree to be accountable for unmet needs? Who will redistribute mental health resources? The CMHC catchment area concept is an attempt to operationalize this accountability issue. Will private care systems accept this concept? According to the task force report:

> To date the private sector has not demonstrated . . . its capacity to deal . . . with the full range of national mental health problems. . . . Among these areas of deficiency may be cited the following:
>
> 1. Failure to meet the needs of emotionally disturbed and mentally retarded children and adolescents and their families. . . .
> 2. Failure to meet the needs of the poor. . . .
> 3. Failure to meet the health needs of the chronically ill, including psychotics, the aged, and victims of organic brain syndromes. . . .
> 4. Failure to make any major impact on the treatment of hard drug addicts, alcoholics, mentally retarded, the delinquent and criminal population, and the "criminally insane." (1, pp. 20, 21)

If private practice allows the provider to declare almost unilaterally the conditions of his practice, especially in regard to whom he will and will not treat, then the accountability of a private care system seems to rest with the provider to the provider. The public care system, including public mental hospitals and CMHCs, has evolved because of the previously noted failure of the private sector to meet the needs of the groups mentioned by the task force. It is clear that private care systems have not included in the past those populations least able to afford or obtain care. To the extent that national health insurance will enable these groups to get care, it is incumbent on both the public and private care systems to develop accountable responses to their demands for care.

It is also essential that objective research designed to

assess the quality of care be stepped up and that requisite standards of care be established so that peer review can be more than a ratification of the status quo. The taxpaying public has the right to get the most from its dollar, and private care systems must open themselves for public review and comment.

The efficiency of alternative mental health delivery systems must be tested in a broad and objective manner. There is no uniform agreement at the present time on cost measures that can be compared from one delivery system to another. Cost of an episode of illness and cost per patient hour or "encounter" must be considered in relation to outcome. Similar services provided by different professionals—psychiatrists, psychologists, social workers, nurses, and the "new" professionals—must be compared. Cost studies must take differing patient populations into account, and the cost of team care must be weighed against the benefits. The savings that result in other sectors of the health and human service system from the utilization of mental health services must be estimated. Cost/benefit logic needs to be applied to indirect services such as consultation and education.

The task force asserts that the cost of care in the private sector is the same as that in the public sector. In support of this statement, the report cites three references. The first (19) contains no data relating to this subject—only the assertion by the authors that this is the case. The other two references (20, 21) include discussions of unit costs in public and private facilities and state that they are equivalent. It should be noted, however, that equal unit costs do not necessarily mean that the cost per episode of treatment is equal. One facility may be providing an average of 6 units at unit cost x while another facility is providing an average of 12 units at unit cost x to produce the same result. Many factors, including the nature of the populations and problems served, differences in outputs or results, and definitions of an episode of care, complicate the assessment of cost. The simplistic approach of the task force does not provide an answer to the question of the relative cost of private versus public care. While it may be that the private sector can provide care more efficiently than the public sector, data supporting this hypothesis are not currently available.

CONCLUSIONS

There are no clear data available to permit adequate assessment of or definitive conclusions about the current relative roles of the public and private sectors, however defined, in the provision of mental health services. Each has a significant role to play and, as the task force report indicates, a balanced mix of the two is essential. Therefore, it is premature at this time to assert the superiority of private care over public care. This issue is complex and requires thoughtful distinctions among public and private organized care systems and solo practice, with public choices being made on the basis of correct interpretations of reliable data and accountability to the people.

The issues we have discussed in this paper remain incompletely resolved. What is clear, however, is that patients need accessible services that are effective and efficient. Representatives of both the public and the private sector of psychiatry would agree that mental illness should not be granted a second-class status by national health insurance proposals and that the right to health includes the right to emotional well-being.

The Clinical Research Ward as a Therapeutic Community: Incompatibilities

BY LOUIS H. REICH, M.D., AND BRIAN L. WEISS, M.D.

The authors discuss the numerous incompatibilities between the clinical research ward, with its emphasis on the collection of baseline and treatment data, and the therapeutic milieu environment, with its emphasis on an open door, team orientation, and nonauthoritarianism. They posit that the two orientations may be mutually destructive and that the therapeutic milieu may not be the best treatment setting for patients with schizophrenic or certain affective disorders. Two case histories illustrating these ideas are included.

THERE HAS BEEN a rapid proliferation of inpatient psychiatric research wards over the past decade, partly because of the growing emphasis on clinical psychobiological and psychosocial research in psychiatry. However, little has been written documenting practical problems such wards consistently encounter (1–3). In particular, the type of clinical setting within which the research is conducted may vitally affect the "success" of the research and thus of the ward. The current fad in psychiatric units has been the therapeutic milieu, established according to the principles of government by the patient community. For reasons of prestige (4) or other factors, this type of ward has become exceedingly popular.

This article is based on our experience in helping to establish a clinical research ward designed to operate as a therapeutic community. The primary purpose in organizing such a ward was to study psychobiological measurements, especially sleep, psychomotor activity, and circadian rhythms, in affective disorders and schizophrenia. We anticipated inevitable conflicts between research goals and therapeutic interests (1–3, 5); our practical experience now suggests that running a research ward in the form of a therapeutic community may be an attempt to create a partnership between antithetical concepts.

SETTING

The clinical research ward at the Western Psychiatric Institute and Clinic, University of Pittsburgh School of Medicine, is a 26-bed inpatient unit that maintains hospitalized patients for an average period of six to eight weeks. Informal and written consent for participation in the research procedures is obtained from all patients and their families at the time of admission. Research procedures include not only the completion of questionnaires, psychological testing, and other less technical approaches, but also blood tests, nightly sleep electroencephalograms, continuous 24-hour monitoring of motor activity, and the use of double-blind drug studies. The majority of the patients admitted to the unit have major affective or schizophrenic disorders.

Sleep, motor activity, certain blood measurements, and clinical characteristics are investigated during the natural or baseline state of the illness, i.e., before the initiation of drug treatment, and during psychopharmacologic intervention. On occasion, this mandates withdrawing patients from medication and maintaining them drug free for a minimum of two weeks. The effect of psychotropic medication on these biological measurements is then studied through double-blind techniques.

Complementing the therapeutic milieu, all patients receive individual psychotherapy, group therapy, and family therapy. There are approximately 30 full-time staff members, including 2 staff psychiatrists and 3 psychiatric residents.

RATIONALE FOR THE THERAPEUTIC MILIEU

The therapeutic community has occasionally been presumed to be a beneficial treatment setting for a clinical research ward because it provides a model in which the patient is likely to behave as a collaborative ally and to participate actively in the collection of data (1, 2). With the research ward structured as a milieu setting, it was anticipated that the investigative efforts would lose much of their dehumanizing qualities and that a syntonic balance between research and treatment could be established.

We also expected that the well-structured milieu environment could significantly assist in delaying the administration of active medication in the control of psychotic patients and that the milieu might enhance any placebo effect. Furthermore, although no real data exist to support this idea, we believe that the incidence of spontaneous remissions may be higher in an active milieu program than in a locked, regressive ward setting. Biological data collected during spontaneous remission are considered to be extremely important, especially in investigations of the switch processes in psychiatric illnesses.

But perhaps the more compelling motivation behind our choice of a therapeutic community was the prevailing

At the time this paper was written, Dr. Reich was Assistant Instructor and Dr. Weiss was Assistant Professor, Department of Psychiatry, Western Psychiatric Institute and Clinic, University of Pittsburgh School of Medicine, Pittsburgh, Pa. Dr. Reich is now Staff Psychiatrist, U.S. Air Force Medical Center, Keesler Air Force Base, Biloxi, Miss. 39534. Dr. Weiss is now in private practice in Miami, Fla.

The opinions expressed here are those of the authors and do not necessarily reflect the views of the Department of the Air Force.

social climate in psychiatry. Complete with open door, team approach, and patient government, the therapeutic community projects an image of enlightenment—offering freedom, dignity, and responsibility to the psychiatric patient (4, 6). In fact, as Maxmen and Tucker (7) pointed out, milieu treatment has become so popular that "no self-respecting hospital psychiatrist could ever confess to *not* running a therapeutic community."

While the milieu approach may well be overused, it is specifically indicated in the evaluation and correction of disturbances in psychosocial functioning. With its emphasis on group and family interaction, the milieu setting can effectively rehabilitate the patient with interpersonal difficulties by teaching him basic psychosocial skills (7–10).

CONFLICTS

While some authors (1–3, 5) have enumerated a variety of basic issues that place clinical treatment aims in conflict with research objectives, no one has specifically discussed the applicability of milieu therapy to a biologically oriented research ward, even though this treatment modality has been in popular use on research wards. In fact, we are of the opinion that a number of factors inherent in milieu treatment make it inimical to pursuing the study of biological measurements in disorders of cognition and affect. The therapeutic community and the research ward may be considered antithetical concepts, not only in their goals but also in their approach to patients, staff decision making, and treatment of certain disease entities. The rapid relief of suffering may preclude the accurate collection of baseline data, and vice versa.

Fundamental to the therapeutic community is the establishment of an atmosphere that encourages patients to take active responsibility for themselves and others. Instead of being passive recipients of the staff's therapeutic efforts, the patients are expected to participate actively and become agents of change themselves (8).

The research patient, on the other hand, is required by the very nature of his admission contract to be a more passive figure and to comply with the mandate of the staff. He "cannot" refuse research procedures (2). In return for agreeing to participate in research, the patient may receive free clinical care. While the patient may be a collaborative ally theoretically, he is actually a passive consenter. Collaboration appears in such minor areas as collecting urine specimens, filling out self-rating questionnaires, or recording time spent off the ward. Major decisions, such as use of medication or passes out of the hospital, are decided by the ward chief, who expects the patient's passive compliance and even relies on it. Indeed, since research decisions are nonnegotiable, it is only through the patient's ready acquiescence that the protocol can be conducted smoothly and efficiently.

In milieu treatment, community considerations predominate over individual ones, while the opposite holds true for the biological research ward. It is this emphasis on the community and community goals which makes this modality useful in inculcating appropriate psychosocial skills (7, 9). Disorganized or aberrant thinking, deviancy, dependency, or other pathological behavior may be quashed and considered impermissible in the milieu, as it would be in society at large.

The research ward, however, either openly tolerates or passively encourages pathologic behavior in the attempt to collect baseline data on untreated natural disease states. Whereas in the milieu setting a patient with an escalating psychosis might be chemically or physically restrained for the comfort of the community as well as to demonstrate the unacceptability of such behavior, on the research ward this behavior is endured, recorded, and valued as an example of psychosis in the pure state.

Milieu therapy readily and expediently imposes controls on symptomatic or pathologic behavior (9) in an effort to impart and teach psychosocial skills. On the other hand, the research clinician may fail to employ the milieu to enforce proper therapeutic limits and may neglect to effectively confront the acting-out research patient. The therapeutic community ultimately relies on the active use of medication to control pathologic behavior and to rehabilitate the psychotic patient rapidly to a level of functioning at which he can assume responsibility for himself and, eventually, for others (11, 12). In order to secure optimal research data, however, pathology must not be altered by symptom removal. Consequently, the research patient remains untreated and is kept in the psychotic phase for an extended period of time.

Even after treatment has been instituted a placebo may be substituted and a relapse may be induced because of the double-blind nature of the research setting (2). Such an event is, of course, demoralizing to the individual patient, the staff, and the entire community in the milieu because they are conditioned to espouse the credo, "Have faith in the ward and trust in the effectiveness of the milieu, staff, and patients." The staff feel frustrated and ineffective and may lose confidence in the treatment setting when the patient on placebo fails to improve or relapses (2, 13). This response may be due to the large number of staff in the milieu setting.

At worst, the guilt induced in the staff by the use of placebo in acutely ill patients may be reflected in acting-out behavior by the staff, which not infrequently takes the form of medication mix-ups—an active medication may inadvertently be given instead of the placebo (14).

The therapeutic community, with its air of democracy and alleged narrowing of the staff hierarchy, traditionally employs the team model; all staff have input to the formulation of a treatment plan. When attempted on a research ward, this approach is weakened and made ineffective because medication decisions are actually formulated and transmitted by the clinical chief, who assesses which drug suits current research needs. The same holds true for decisions on hospital passes and any other decisions that affect active protocol patients.

Another universal feature of the therapeutic community is the open door, perhaps the sine qua non of enlightened hospital care (4). This invariable component also interferes with the smooth operation of the biologically

oriented research ward. The open door is nevertheless essential for the milieu's task of intensive resocialization, which includes the goal of letting patients leave the floor on pass, take walks, and slowly acclimate themselves to the outside environment. For example, the continuous 24-hour collection of data on motor activity (which can be telemetrically monitored only when the patient is on the ward) is interrupted and is therefore inaccurate when the patients are traveling on and off the floor. In addition, according to the milieu's emphasis on the patient's resocialization, taking initiative, and assuming responsibility, a rapidly cycling hypomanic patient would be able to leave the ward on extended passes before active medication was initiated. This would result in the loss of much baseline data. Another research disadvantage of the open door policy is the obstacle it presents to keeping illicit drugs off the floor and away from adolescent borderline and schizophrenic patients.

Another concept held in contradiction by the research and the milieu schools is the role of stress. In the milieu setting, stress is considered an integral part of living with which the patient must learn to contend. It is therefore only minimally reduced and usually not eliminated. The numerous groups, family meetings, and patient-staff meetings ensure frequent stressful situations (8, 10, 15), which may produce factitious findings in the monitoring of a number of biological measurements such as observations of motor activity or levels of corticosteroids or catecholamines. A research ward that emphasizes supportive approaches and avoids stress-inducing situations may be more efficient in studying psychosis and the effect of medication on a variety of biological measurements. The combination of an open door, with patients on and off the ward, and frequent stressful groups may have resulted in our finding (16, 17) that monitoring motor activity or steroid or catecholamine levels was more fruitful in the evening hours, when the patient was free from external pressures or ward activities.

MILIEU TREATMENT AND SPECIFIC DIAGNOSES

We have attempted to demonstrate how certain principles basic to milieu treatment are, in fact, counterproductive to the functioning of a research ward studying biological phenomena in psychiatric disorders. Not only do certain aspects of milieu treatment interfere with the orderly collection of research data, but the specific disease entities under investigation, such as schizophrenia and the affective disorders, are often ill served by an active milieu setting.

As described, the milieu setting, with its emphasis on forced social interaction and participation in various group meetings, provides complex and intense stimulus input for the disorganized schizophrenic patient. The seclusiveness and isolation of the schizophrenic patient represent not merely pathology but also a defense that should be respected until the patient can contend with increased stimulation (18, 19). The environment for schizophrenic patients should be simplified and unambiguous; patients should receive cues in clear, concrete language (12, 20, 21). That archetypal milieu phrase "talk about it" serves no such function for the disorganized schizophrenic patient. It is for these reasons that others have warned of the deleterious effect of an intense milieu on schizophrenic patients (11, 12, 18, 22) and have recommended reduction of arousal and removal of stress (16, 18).

Case Reports

Case 1. A 26-year-old single man who had been diagnosed during his only previous psychiatric hospitalization as an acute schizophrenic was admitted to the research unit because he was complaining of suicidal ideation and because the admitting physician noticed some delusional ideas about food. On admission, the admitting resident described the patient as a "distant, depressed white male with flat affect, speaking somewhat tangentially. Completely oriented, intellect and memory good."

The patient had not been taking any medication before admission and he was kept drug free on the ward. Although he was noted to be "preoccupied with transcendental meditation," both nursing notes and physician's progress notes over the next several days documented his cooperative attitude, his willing participation at meetings, and his help with the other patients.

However, by the fifth day of hospitalization, he was noted to be increasingly anxious and more isolated. His depression seemed more severe, he was no longer able to sit through community meetings, and his behavior became intermittently inappropriate. He began refusing to eat and he "attempted to elope from the unit, saying he needs to get out to get his thoughts together. ... [He is] afraid of contaminating other patients with his evil" (nursing notes).

By the sixth day of hospitalization, he was requesting medication. His sleep was becoming increasingly disrupted, he made a suicidal gesture, and he was placed in a cold wet-pack upon request. "He felt he was losing control. He had to be medicated" (nursing notes). This occurred at 1:00 a.m. on the seventh day of hospitalization, by which time he was actively psychotic. Phenothiazines were administered at this time, and he quickly responded favorably.

With the benefits of the therapeutic community accruing in the area of psychosocial rehabilitation, those patients with difficulties in this area would most benefit from a milieu setting. The elderly depressive patient with no previous psychiatric hospitalization and with a satisfactory marriage, work history, and social history would probably do better elsewhere. Such a patient might find a therapeutic community a meaningless experience at best; at worst he might become disorganized by the complexities of a milieu treatment.

Case 2. This 59-year-old man had no previous psychiatric history. He owned a bar, had been married for 35 years, and had three grown children. Three months before admission he began experiencing apprehension concerning the impending sale of his bar and began ruminating about whether he could fulfill his financial obligations. Over this period he became increasingly anxious, agitated, and irritable. He experienced interrupted sleep, diminished appetite, a 10-pound weight loss, constipation, anergia, and social withdrawal.

On admission, he appeared neat and cooperative, but guarded. He frequently wrung his hands, showed a worried ex-

pression, and had a depressed affect. He blamed himself for stealing from a business partner. There was no evidence of psychosis and he had been drug free. He received no medication at this time on the unit.

The second evening after admission he expressed fear that he or his family might be harmed in the hospital; the following day he believed his food to be poisoned. He feared transfer to a jail for having cheated his partner. Nevertheless, during the first four days of hospitalization he responded well to staff reassurance and was able to sit through meetings and even to make appropriate, although infrequent, comments. On the sixth day of hospitalization his controls became tenuous. He made innumerable phone calls home to convince himself that his family was there and tore his clothes in anguish. Yet when his family visited that day he regained control. The next day his agitation and delusions persisted and he openly expressed concern and worry over all the unit activities.

On the eighth day of hospitalization he lost control. Fearing harm from the staff, he barricaded himself in a room armed with a lamp and started striking out. At this point the research protocol was abandoned and medication was started. He responded well to the medication and was discharged to his home. Neurological investigation during his hospital stay had been entirely normal.

Certain patients with character or so-called borderline disturbances regress markedly in the democratic, nonauthoritarian environment of the milieu (23–25). Since these patients invariably display better controls than do overtly psychotic patients on admission, the staff assumes they can function reasonably well and will work readily toward the community's goals. However, this type of patient quickly discerns and discards this expectation as he observes the more disorganized patients receiving intensive staff care. He may then reject taking responsibility for himself or others. Longingly noticing other patients who receive continuous staff attention, yet with his own insatiable need for gratification remaining unmet, the patient may yield to regressive temptations. Ultimately, in the hope that self-injury will gratify his dependency needs by evoking care and attention from the staff, the patient may resort to self-mutilative or suicidal gestures or begin to use illicit drugs on the ward (25, 26).

Unfortunately, the remedy for countering such regressive dependent behavior, i.e., cohesive and united staff attitude, is actually a difficult and unlikely accomplishment in a heavily staffed, team-oriented, nonauthoritarian milieu. It is of interest that these patients can quickly reverse their regressive behavior in a custodial, authoritarian, unpleasant environment (1, 4).

In addition to the numerous other incompatibilities between the clinical research ward and the therapeutic milieu described in this paper, we also point out that the extra cost of the milieu setting, in terms of the necessity for increased staffing and the apparently accelerated loss of research patients during the protocol period, must be carefully considered.

Limitations and Values of Evaluation Techniques in Psychiatric Education

BY S. MOUCHLY SMALL, M.D.

The author presents a summary of the major evaluation techniques now available and discusses the values and limitations of each. He concludes that only by the use of many evaluation instruments during the resident's period of training can some estimate of clinical competence be approached. Even with this multiplicity of testing instruments, the validity of predictions of a psychiatrist's performance can be determined only in terms of probabilities.

THE GOAL OF MEDICAL EDUCATION is to produce a physician with the knowledge, skills, attitudes, and judgment that he will use to provide professional services of high quality. Having stated the goal, it is then necessary to describe the factors involved in achieving it in more specific operational terms for the construction of curriculum and, ultimately, for the evaluation of both the program and its graduates.

Knowledge can be stated in a fairly precise fashion, although the expansion and diversification of curricula reflect its complexity. Skills can also be defined, but they are less subject to quantification than are understanding and factual knowledge. Attitudes and judgment are much more difficult to outline or measure and are usually expressed in a more qualitative fashion than other measurements (1).

Under the present system, responsibility for undergraduate and graduate education is divided between medical schools and hospitals. There is a lack of coordination between these responsible institutions except in instances where faculty and staff overlap. Examinations in medical colleges have traditionally covered the basic sciences and clinical subjects separately. Their application (subsumed under the general term "clinical competence") is minimally tested in the schools but has been emphasized during the internship and, more particularly, during specialty training. The evaluation of clinical skills stresses diagnosis, management, technical skills, and patient-physician relationships rather than theoretical knowledge. Recently, increasing consumer demands for professional accountability have led to an even greater emphasis on aspects of competence that are clinically relevant and significant.

Evaluation techniques for psychiatric residents must change as the educational and scientific bases of medicine and psychiatry progress and as changing patterns in the health care system evolve. Furthermore, the all-embracing nature of modern psychiatry, including the contributions made by disciplines ranging from biophysics to ethology, involve psychiatric subspecializations of all sorts—child psychiatry, community psychiatry, forensic psychiatry, administrative psychiatry, and the various therapeutic modalities such as psychoanalysis, dynamically oriented psychotherapies, family therapy, and behavior therapy. Such diversity makes it impossible to incorporate the teaching of psychiatry into a single educational sequence or testing program (2) and requires an appraisal of what is considered essential as differentiated from elective.

Holland and Stoller (3) formulated the core characteristics of a psychiatrist, i.e., the psychiatrist has comprehensive knowledge and understanding of the physical and behavioral dynamics of the human being, possesses diagnostic skill and therapeutic judgment, operates within the professional code of medical ethics, and has a deep sense of responsibility. With these characteristics as an orientation, we must come to some agreement about the level of knowledge and skill the psychiatrist must possess and then design and use a great many evaluation instruments to determine whether the resident has reached the required levels. It would also be desirable to determine if the psychiatrist in practice continues to update his cognitive and technical skills and maintain a level of performance comparable to his performance at the time of examination as a resident.

Effective methods for evaluating the psychiatric resident's general knowledge and clinical competence are required to ensure that he has mastered the fundamentals of psychiatry. What these essentials or goals of the residency should be often reflect the self-image held by the group of successful specialists who participate in constructing the curriculum and developing professional criteria to achieve these objectives. Even when the goals are not very specifically elucidated, most training programs agree on the time frame (usually three years for psychiatry) and the means by which they are to be achieved.

Testing may be used in a number of ways, including the following: 1) to protect the public by ensuring a certain minimum of professional competence and safety, 2) to provide data for programmatic decisions about the teaching-learning program and the abilities of the instructors and supervisors, and 3) to define areas of strengths and weaknesses for the individual resident; he can use these in a constructive fashion to improve himself.

The basic limitation of any examination tool for clinical competence is that it presumes to be predictive in na-

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Dr. Small is Professor and Chairman, Department of Psychiatry, and Buswell Research Fellow, State University of New York at Buffalo School of Medicine, Buffalo, N.Y. 14214.

ture; it supposedly predicts whether or not a given candidate is likely to be competent in his future clinical dealings. An examination cannot pretend to be infallible because it cannot encompass future conditions or the future development of the examinee. It should be obvious that the predictive validity of any examination can be seen only in terms of probabilities, not in terms of certainties (4).

There is probably no technique, including peer review and direct observation of clinical performance, that really helps us to predict with a high degree of reliability at any given moment in time how a physician will perform in the future in a private, unobserved clinical situation. Most of us can probably attest to the fact that we show changes in attitude, approach, clinical technique, and formulations that are consciously and unconsciously modified by the presence of an observer or by the recording of the patient-doctor interaction (5).

Thus the most serious universal limitation of all individual and group testing is probably the lack of certainty that the abilities demonstrated on the examinations can and will be used in providing medical services and that an acceptable standard of medical care will be ensured.

Although our evaluative techniques are imperfect, we cannot delay until the mechanisms for testing are ideal. We need to participate in a continuing analysis of the changes in goals and objectives and to reflect them in our evaluation methodologies. Testing may be adequate for certain aspects of residency training; in other areas we may have to settle for an analysis of effort. For example, it might be of value to know how much a resident reads, how many hours he uses for study in the specialty, his regularity in attending rounds, conferences, and seminars, whether he maintains good medical records, the concern he shows for patients, and other aspects of his day-to-day clinical work. Again, there is no evidence that these activities have a high degree of correlation with clinical effectiveness. Nevertheless, their "face validity" is compelling.

EVALUATION PROCESSES

At varying points in the resident's educational program and development, it is beneficial to evaluate knowledge and cognitive understanding in a longitudinal fashion. This allows the resident to compare himself within the program's time frame as well as with his peers. Although it is an unproven assumption that these measures relate to clinical competence and skill, it seems clear that clinical effectiveness and high quality performance are patently impossible without a cognitive base.

Oral Examinations

Oral examinations are notoriously low in reliability; they become less effective, more expensive, and more time consuming as the number of examinees increases. At present they are used primarily in psychiatric board certification examinations to evaluate interviewing skills, attitudes, capacity for empathy, judgment, and the clinical application of knowledge and understanding. For example, an insensitive candidate who is a poor observer, who treats the patient brusquely, who uses inappropriate language, who doesn't follow up cues given by the patient, who does not make effective contact because he is too busy taking notes, and who omits obvious possibilities in discussing differential diagnosis, therapeutic options, and psychosocial factors would be considered inadequate or unsafe for that particular clinical situation.

Improvement in scoring and reliability is usually achieved if a checklist of items to evaluate the candidate is used. Ideally, the only variable should be the examinee's clinical competence, but this is not the case because different patients as well as different examiners are involved. Some of the variables may be minimized by using simulation techniques with professional actors trained to portray certain patient attitudes, feelings, and thoughts. Some improvement in reliability has been shown when videotapes of interviews have been used.

Essay Examinations

Essay questions are easy to compose and give the resident an opportunity to show how well he can organize and express his thoughts concerning the most complex types of clinical situations in an orderly, logical, and lucid manner. However, essay questions have many drawbacks and limitations. Proper sampling of such an extensive field as psychiatry within reasonable time limits is impossible. Increasing the number of questions, shortening the time allowed for responses, and allowing the examinee some choice of questions decrease the sampling error but do not overcome the halo effect of grammar, spelling, and legibility of handwriting or the effect of repeatedly demonstrated lack of test reliability shown by comparing scores of two or more examiners. Reliability is poor even when the same individual scores the same group of responses after a time interval (6).

Multiple-Choice Tests

The technique of multiple-choice tests was applied to medical examinations about 1951. As a result of extensive experience, the variety of multiple-choice questions has been cut back to three basic types.

1. One-best-response type (type A). This is the type most commonly used. Each item (question) consists of a stem that is a statement, case history, chart, graph, or picture followed by four or five suggested answers. Only one of the answers is correct; the others are called distracters. The best or most appropriate response must be selected. Some of the distracters may be partially true. With a five-choice item, there is a 20 percent chance of guessing correctly.

2. Matching types (type B). A list of lettered headings (usually five) is followed by a list of words or phrases. The examinee selects the heading most closely related to the words or phrases. By inserting "none of the above" as an entry in the lettered heading, the item is made much more difficult because the examinee must think of possible associations other than those stated.

Another form of matching item (type C) offers four possible answers. The candidate is directed to select response A if the word or phrase is associated with A only, select B if the word or phrase is associated with B only, C if associated with both A and B, and D if associated with neither A nor B.

3. Multiple true-false types. In type K of this group, the stem may be in the form of a statement, question, case history, clinical data, or pictorial material. This is usually followed by four unequivocally true or false statements. Five combinations of responses are usually offered. These are not mutually exclusive but one combination must be selected. This type of item tests the depth of the examinee's knowledge and understanding of several aspects of a disease, process, or procedure.

With type-X multiple true-false items, the candidate scores any combination of rights and wrongs. The directions for this type of question are less complex and the examinee gets some credit for partial knowledge. However, it has the disadvantage of weighting a particular item too heavily. Furthermore, a comparative study of multiple true-false items using types K and X does not show significant differences in the rank order of the candidates for reliability and effectiveness (7, pp. 20–31).

The use of multiple-choice tests in medical examinations provides a vastly improved sampling, a high degree of reliability, objective machine scoring, and valuable information about areas of strength, weakness, and misconception. Computer printouts give P values (the percentage of examinees who answer each item correctly) and biserial correlation coefficient values (r). These show how well each question discriminates between well-qualified and weak examinees and allow for constant improvement of the item by eliminating distracters that are not performing well.

The criticism that most written examinations test only memory (8) confuses the issue by equating cognitive understanding and knowledge with straight recall. Knowledge consists of such things as facts, ideas, explanations, meanings, processes, procedures, relations, and consequences (9). The examinee must think and conceptualize as well as remember. Well-written test items require the candidate to retrieve, select, organize, and apply his knowledge. Too often the fault is not with the form of the item itself but with the writer. We need to develop and train more competent and highly qualified psychiatrists who are willing to devote enough time to write meaningful, significant, relevant, and effectively discriminatory items of moderate difficulty. Only then will we have explored the full potential of this type of technique for psychiatry.

Patient-Management Problem Tests

Tests involving patient-management problems typically begin with the presentation of a brief clinical history, physical examination, and routine laboratory tests that are representative of diagnostic and management problems thought to be important or signal in nature. The examinee is required to select the most appropriate courses of action out of a given number. In selecting an answer, he erases a portion of a plastic overlay, revealing information underneath. The information revealed may be useful or may merely disclose that his selection is noted. Armed with this new information, the examinee proceeds to more detailed clinical problems about the same patient (10).

The content of such tests is obtained by use of the critical incident technique. Physicians with acknowledged expertise are asked to report examples of conspicuously good or poor (inappropriate) clinical practice. From thousands of such incidents, major areas of clinical performance are defined, i.e., history taking, physical examination, use of tests and procedures, diagnostic acumen, treatment, judgment, skill in implementing care, physician-patient relationship, continuing care, and responsibility as a physician. These definitions provide test makers with ideas of what is to be tested (5).

This type of testing obviously differs from real clinical situations in which the examinee has to originate alternatives rather than select from multiple choices. The scoring gives credit for correct decisions and penalizes the candidate for omitting important procedures or choosing those which are harmful to the patient. Correct selections made from a relatively large number of alternatives give the examinee additional information that will often help him with the next problem concerning the same patient.

According to Hubbard (7) the reliability of this type of testing is generally at the level of .80 to .85 (7, pp. 40–50). Unfortunately, the interdependency of related responses has the effect of decreasing the reliability of the test. Schumacher (11) questioned the value of this format on the basis that a specialty examination in internal medicine showed no significant performance increment after two years of residency training in that specialty. Similar findings have been reported for residents in orthopedic surgery (12).

Despite these adverse reports, this type of examination appears to have validity and has considerable appeal to the examinees. According to my personal experience, which has been corroborated by others who have constructed many such items, special expertise is required to construct such problems without giving away information that enables the examinee to backtrack to previous questions about the same patient and correct his errors. This can be avoided with a computerized test or with special techniques yet to be evolved. Furthermore, there is a wide range in discriminatory power between various problems of this type.

We have yet to learn how to refine this particular technique so that it may show a significant difference between well-trained physicians and those who are less clinically competent. However, it seems that this format, coupled with other types of tests, may have the potential for achieving a significant advance toward the goal of developing standardized, reliable, and valid instruments for evaluating some aspects of clinical competence.

Peer Review

The approach of peer review has value because it measures actual clinical effectiveness as it is evaluated by cli-

nicians. This technique suffers from practical uncertainties such as variation in definition of levels of competence, inadequate sampling, logistic difficulties when it involves large numbers of professionals, and great difficulty in proving reliability and validity. It is, however, unambiguously focused on the presumed concern of all tests in medicine, namely, the quality of care actually provided for real patients.

Simulation Techniques

There is a large number of simulated clinical situation techniques, including the computerization of methodology for patient-management problems. These vary in their approximation to real-life situations. Testing with films or film clips is expensive, especially if color film is used. Many of the test items in specific simulation tests have been either too easy or too difficult and have failed to discriminate between a more able and a less able group. The use of filmed material has been abandoned by the National Board of Medical Examiners on part III of its test (13).

There are many types of audiovisual presentations. One of these involves the examinee's asking and answering clinical questions regarding a patient whose complaints and history have been presented by a computer. The computer answers the examinee's questions about the clinical situation and records the examinee's working diagnosis and plan for management and treatment. Such techniques are hampered by large development costs and the complexity of the analytic work necessary to provide widely applicable results.

CONCLUSIONS

Of necessity, this short paper can provide only a summary of the major evaluation techniques now available. The discussion of their values and limitations is similarly scanty. What is clear is that only by using many evaluation instruments during the resident's period of training can one approach some estimate of the elusive goal of clinical competence. Even with these instruments, it is apparent that predictive validity for a psychiatrist's performance in the future can be determined only in terms of probabilities. The complexity of the newer techniques strongly suggests that evaluation research and teaching seminars for question writers have now become imperative if we are to improve our testing methodologies.

Psychoemotional Aspects of Mastectomy: A Review of Recent Literature

BY MICHAEL J. ASKEN, M.A.

The author reviews the recent literature on the psychological aspects of mastectomy, including psychological reactions to the procedure and appropriate intervention strategies. He discusses individual and familial fears and concerns related to mastectomy and emphasizes the importance of preoperative counseling and postoperative rehabilitation.

THE IMPORTANCE OF psychological factors in physical medicine has long been recognized by medical practitioners. Jaco (1), for example, stressed the importance of treating the entire patient rather than collected and selected parts. Certain medical procedures save lives but also result in some degree of functional loss or disfigurement for the patient. This paper will consider the psychological aspects of mastectomy, which is such a procedure. I will present a review of the literature dealing with both psychological reactions to the mastectomy experience and appropriate therapeutic interventions.

PSYCHOLOGICAL ASPECTS

While mastectomy performs a gratifying service by saving a woman's life, her appreciation is muted by the price she must pay for that service—the loss of a breast and permanent disfigurement. Within the value system of American society, that price is a considerable one. The following statement describes the thoughts and feelings of a mastectomy patient:

> The only data my brain registered were that breast cancer with metastases has a short-term survival rate and I was mutilated.
>
> From the moment my physician said that I had metastatic breast cancer until two years after my surgery, I was frozen with fear. The people who are supportive to me were so shaken by my unexpected reaction that they ceased to function for me. The threat of death hung over me day and night, but I believe that the mutilation was more traumatic. Living became so arduous I found myself preparing to die on all levels—I stopped buying clothes or refurnishing my home as needed; I arranged my work each day as though tomorrow were not coming; and, finally, I developed a speech pattern which became death oriented. (2, pp. 676, 677)

These words were spoken by a practicing registered nurse, a professional who is medically sophisticated and actively involved with helping others to accept their misfortunes. The impact of the mastectomy experience must, therefore, be exponentially increased for those leading more sheltered lives. Indeed, Roberts and associates (3) reported that 51 percent of their sample of mastectomized women admitted anxiety or depression; the authors concluded that there is an important psychological morbidity associated with all operations for primary breast cancer. Ervin (4) expressed the belief that emotional suffering outweighs physical pain in mastectomy cases.

Generally, the predominant psychological reactions to mastectomy are a sense of mutilation and a loss of feelings of femininity (4–8). Goldsmith and Alday (9) reported that mastectomy raises several fears in women. First, there is the anxiety associated with any major surgical operation. Perhaps more important than this, however, are the fears associated with breast loss: concern over sexual desirability, interpersonal and sexual relations, and, if the woman is married, dangers to her marriage. Third, there is the fear of death, an omnipresent consideration for all mastectomy patients. This fear is not always expressed overtly; it may sometimes undergo unconscious transformation and be expressed as fear of breast loss (although there is probably little reason to doubt the veracity of the latter concern). Mastectomy may assume a symbolic quality in other ways (10). The young patient may have a strong reaction to mastectomy as the operation suddenly forces her to confront her own mortality. In the older patient, mastectomy may confirm the debilitating effects of old age.

Lymphedema is another area of concern to women who undergo mastectomy (5). Healey (5) reported that the psychological fears about lymphedema include: 1) self-consciousness of the enlarged arm in the presence of others, 2) difficulty in fitting clothes, and 3) changes in lifestyle affecting social behavior.

Some women harbor myths and unanswered questions about the operation and its results. Klein (10) reported several misconceptions commonly held by the patient, including the belief that cancer always recurs or kills, that she will be perceived by others as untouchable, and that she is in some way responsible for her cancer. The patient may have many questions that she considers in-

Mr. Asken is an advanced doctoral student and Instructor, Department of Psychology, West Virginia University, Morgantown, W. Va. 26506.

The author wishes to express his appreciation to David J. Withersty, M.D., Chief of the Inpatient Service, Department of Behavioral Medicine and Psychiatry, West Virginia University Medical Center, for his help in the preparation of this paper.

appropriate at the time of surgery; consequently, they may never be asked or answered. This lack of knowledge may cause considerable anxiety. The patient may wonder how she can keep her bra from riding up on the operated side and what sorts of special bathing suits are available to her (11).

The loss of a breast leaves the woman in the unusual situation of having only one breast, a condition that is apparently fraught with ambivalence. Leis (12) reported that much is made of the psychological importance of the remaining breast, which may be cherished as a badge of motherhood, a sign of femininity, and an important psychosexual symbol. Leis also noted, however, that the second breast remains as a nonfunctioning organ: few women display it as a "questionable" sexual stimulus next to a mastectomy scar, and few allow it to be used during the sexual act. Some doctors will not permit the remaining breast to be used in breast feeding. There is also the problem of disrupted body symmetry. Finally, patients may live with the fear of recurrent cancer in the remaining breast. Thus, this breast has both a positive and negative value to the patient, resulting in vacillating ambivalence.

Klein (10) observed that the adverse psychological effects from mastectomy may also affect the patient's family. The malaise may be transmitted by the patient herself through her own distorted self-view as a person unworthy and unable to readapt to her normal role. A husband's perceived inability to help his wife may cause guilty resignation to a vitiated and destructive marriage. Children may develop school problems as a response to their mother's inexplicable depression. Quite apart from the effects that a patient's altered mood may have on the family, the husband in particular may have some very real mastectomy-related concerns (10). Foremost is the question of his wife's survival. He may also be unsure how to respond to his wife after her operation and unsure of what new needs she will have for him to fulfill. Many husbands who are full of uncertainty and conflicting emotions may express their concerns by withdrawing and retreating from the situation; the wife may interpret this behavior as rejection, an especially psychologically detrimental misperception on her part.

INTERVENTION

Given the overall trauma of mastectomy, intervention with the breast cancer patient must involve both physical and psychological considerations. It has been suggested (13) that rehabilitation after mastectomy must be approached on three planes to cover both aspects successfully: physical, cosmetic, and emotional. Similarly, Dietz (14) proposed that the goals of mastectomy rehabilitation are the maintenance of the range and function of the arm and shoulder, the restoration of external appearance, and psychological adjustment (i.e., acceptance of breast loss, reintegration of the self-image as being worthy of love and the rewards of life, and adjustment to the possibility of cancer recurrence in the following years [10]). Also, the goal of intervention for the patient beyond help is to provide comfort in the terminal stage (15).

Physical Rehabilitation

Rehabilitative measures for mastectomy patients generally fall under the rubric of primary prevention, i.e., the prevention of adverse psychological reactions to the procedure. The preventive steps are instituted either pre- or postoperatively. In many cases the procedures and their timing are interchangeable or repeatable. The implementation schedule will most probably be dictated by the schedule of medical procedures, since the diagnosis and treatment of breast carcinoma are often almost concurrent (7).

The prevention of iatrogenic physical degeneration is accomplished through the use of both pre- and postoperative physical therapy. The use of physical therapy has been described by Beeby and Broeg (13), who outlined three objectives for the procedures: 1) to obtain and maintain complete ranges of ipsilateral and shoulder motion, 2) to prevent postural deformities such as protracted scapulae and kyphosis of the vertebral column, and 3) to counter all possible ill effects of lymphedema. Preoperative physical therapy is designed to prevent postoperative pneumonia, muscle degeneration, pooling of lymph fluids in the extremities, and postural deformities. Postoperative physical therapy includes introduction and explanation of procedures, evaluation of abilities, appropriate exercises, and discharge evaluation with instructions for home exercises.

Cosmetic Reconstruction

Emphasis on the cosmetic plane is, of course, one of the central issues involved in the controversy over the extent of surgical procedures required to adequately treat breast cancer. Beyond this problem, however, breast reconstruction is the only solution to the problem of disfigurement. Millard and associates (6) and Freeman (16) suggested that offering the chance for breast reconstruction even before the breast is removed can be of great comfort to the patient. Of course, any safe procedures that limit the destruction of the breast are desirable; to accomplish this, Millard and associates (6) offered a procedure for saving the uninvolved nipple. The nipple-banking procedure consists of temporary grafting of the nipple until it can be replaced onto the reconstructed breast. The authors found this procedure to be a great morale booster, giving the woman something to look forward to and serving as a token of the doctor's faith in her recovery. It has been suggested that women should be allowed to have simple breast reconstruction postoperatively (8). The use of silicone implants has been cited as a quick method that produces "no cosmetic triumphs" but often obtains "astounding" psychological improvement (7).

Counseling

The obvious purpose of cosmetic reconstruction is to ease psychological adaptation, but preoperative and postoperative counseling (preferably both) are also manda-

tory. Dietz (14) suggested that the use of counseling is dependent on the needs of the patient but that its goal should be to prescribe an individually suitable rehabilitation program. The following counseling procedures are arbitrarily designated as either pre- or postoperative measures, depending on their classification in the literature; however, their administration is flexible.

Klein (10) presented examples of content to be covered in preoperative counseling with the mastectomy patient. He suggested that the patient should be helped to consider what to tell the significant people in her life about her situation. Children will inevitably become aware of the change in familial routine. Younger children may feel deserted by a hospitalized mother, and older children may put together their own ideas about the surgery from bits of conversation; special consideration should be directed to the teenage girl, who may be wondering if she will suffer the same tragedy. Frankness is advocated as the best means of combating emergent fantasies. Adult discussion also provides a good model of healthy coping patterns.

Counseling also attempts to help the patient to anticipate the future. The length of rehabilitation and the role the patient must play in it are important areas for discussion. Harrell (2) reported that the function of the counseling interview is to provide information to the patient. She suggested that the patient be assured that crying spells are normal and to be expected, that sleeplessness or nightmares may occur, that some numbness in the arm is natural and no cause for alarm, and that breast forms are available and should provide confidence and comfort. Markel (11) reported that during the preoperative interview patients should be encouraged to express questions of importance to them, and Klein (10) suggested that misconceptions that are held about the procedure and its implications must be dispelled. Klein (10) also cautioned, however, that false assurances must never be given because the future in any respect can not be guaranteed.

In regard to postoperative counseling, Harrell (2) stressed the appropriateness of the postsurgical hospitalization period for primary prevention and secondary intervention. This period provides for continuity of care and also presents a situation in which the patient and family are together so that common problems, questions, and misbeliefs can be attended to. In short, the hospitalization period provides an excellent opportunity for reaching the patient and her family.

Another facet of postoperative intervention reputed to be of value is a mechanism to allow patients to express either residual or newly emerging feelings of concern (10). This goal can be achieved through group therapy, although in all cases individual consideration should be paramount (5, 14). A program that uses a team approach to incorporate many of the points suggested is reported in the literature (17). The team is comprised of the patient, nurse, physical therapist, and recovery worker, who meet daily in a class-type atmosphere. The purposes of the meeting include instruction in beneficial exercises, communication of information about prosthetic devices, and provision of a forum for the discussion of questions and feelings. The strongest factor in this approach is the group itself, in which patients help each other.

The usefulness of prosthetics clinics has been reported by Akehurst (8). The clinic described is held concurrently with joint breast and radiotherapy clinics. It is staffed by a woman fitter and a lay worker who is a former mastectomy patient. Visits by a former mastectomy patient who is currently looking and functioning well is a technique that has great psychological benefits and receives almost universal support (3, 5, 8, 11, 17). Akehurst (8) reported that the use of the former mastectomy patient is vital to rehabilitation, because having suffered the physical and mental effects of the operation, she is the only person who can talk to the patient with real understanding. The lay worker is often part of the Reach to Recovery program endorsed by the American Cancer Society (11) and by medical professionals (4, 18). In addition to workers who are part of this mastectomy rehabilitation program, the society distributes a film entitled "Recovery After Mastectomy," which may be used in place of or as a supplement to the recovery worker (11). A manual on mastectomy written for the patient by Lasser (19) and an article by Aves (20) describing swimwear for the mastectomy patient would also be useful in the treatment of mastectomy patients.

There are two other aspects of postoperative programs that are essential to rehabilitation. The first is the requirement of counseling for the family of the mastectomy patient (10, 21). The second is proper discharge planning to ease readjustment into normal life (5).

The Surgeon's Role

The surgeon or gynecologist transverses the entire experience of mastectomy. In the psychological sphere, his role has too often been avoided or left unfilled (7, 22). Klein (10) reported that the surgeon is central to helping a woman accept the mastectomy. This is so not only because he has the greatest opportunity to help but also because he is perceived as knowledgeable, skilled, and godlike by both the patient and the family and because the patient is eager to believe in his power to cure both the body and the psyche.

Unfortunately, the surgical role presents practical problems that inhibit the surgeon's ability to respond as a palliative psychological agent. Heavy caseloads and the demands of surgery preclude the establishment of more than a fleeting relationship. Despite these inhibitions, however, the surgeon can engage in simple behaviors that will aid in postoperative adjustment. Psychological intervention can begin at the precise moment that the necessity for mastectomy is determined and may be effected by stressing any positive aspects of the situation (such as small tumor size or the short time interval between diagnosis and removal) and by being aware of female and familial concerns and fears. The surgeon may see to it that appropriate ameliorative measures are instituted or administered postoperatively (9). Ervin (4), a surgeon who has been impressed with the psychological morbidity of mastectomy, has outlined a counseling technique he

uses with mastectomy cases that centers on honesty, hope, and the involvement of the husband.

It is imperative to remember, as Markel (11) has pointed out, that in the patient with breast cancer, postoperative treatment and rehabilitation cannot be separated; if rehabilitation has not been accomplished, postoperative treatment is incomplete. To this must be added the necessity of preoperative preparation.

Finally, words written by Harrell (2) once again seem appropriate.

> To save a woman by surgical intervention and then deny her emotional support necessary to form a different lifestyle and accept an altered body image is a contradiction in terms. (p. 676)

EDITORIAL

Greetings and Thanks

THE YEAR 1975 marks the 10th anniversary of the change of editorship of the journal of the American Psychiatric Association. The present editors assumed office with some trepidation. For 32 years the distinguished Clarence B. Farrar had edited the *Journal* almost single-handedly and following him would be no easy task. Fortunately, nearly everyone was kind and helpful and we have survived thus far—this despite the fact that we perforce must occasionally send authors' brainchildren back to them, and this does not make us generally beloved.

We are indeed grateful for the help we have received, and we note that fact in each January issue. We know, too, that when we appeal for help we are encroaching upon the time of busy colleagues, but we always hope that they realize that this is their journal and that their help and expertise help keep it at its present high level. We hasten to add, however, that final decisions must rest with the Editor, and whenever clinkers get into our publication, the responsibility is his alone.

Therefore the Editor, the Managing Editor, the Editorial Board, and the staff take this occasion to especially thank the colleagues listed below for their help from November 1, 1973, to November 1, 1974.

We are grateful to our book reviewers, also, but because they sign their reviews and the readership is thus familiar with their contributions, we have not listed them here.

Unfortunately, in an operation of this size someone's name may be omitted, perhaps someone to whom we are especially indebted. We apologize in advance should this happen, and we would like to hear about our errors of omission and commission.

The editorial staff notes particularly its indebtedness to Dr. Walter Barton and wishes him well in his new venture. We look forward to working in pleasant symbiosis with our new Medical Director, the distinguished Dr. Melvin Sabshin. To Drs. Donald W. Hammersley and Henry H. Work, and to Mr. Robert L. Robinson, Mr. Raymond M. Glasscote, and Ms. Jean Jones—all of the APA staff—go our special thanks for their continued courteous assistance and cooperation.

Our greetings to all of our colleagues and readers and our hopes that their New Year will be the happiest ever.

F.J.B.

The Psychiatrist's Involvement with Aged Patients

BY FLOYD K. GARETZ, M.D.

The author studied via questionnaire psychiatrists' involvement with older patients in relation to their own ages and the nature of their practices. Older psychiatrists see a higher proportion of older patients, advocate more comprehensive treatment, and find older patients more interesting and gratifying. Psychiatrists in general psychiatry and those who have a primarily inpatient practice see the largest proportion of older patients.

LARGE NUMBERS of aged people in the United States experience mental and emotional disorders, yet the elderly appear to underutilize psychiatric services (1–3). Although several authors have investigated this phenomenon (4–6), many questions remain unanswered. The present research is based on a questionnaire study of psychiatrists regarding their involvement with older psychiatric patients.

METHOD

All members of the Minnesota Psychiatric Society who were available for sampling (N=202) were asked to complete a questionnaire that yielded data on their ages, professional interests, and types of practice. In addition, data were collected on their experiences with, perceptions of, and attitudes toward older patients (those over the age of 65). The data were in the form of either continuous variables (age of psychiatrist and percentage of older patients seen) or categorical variables (the remaining data). Correlation coefficients were used for comparison of continuous variables, and categorical variables were compared with each other by chi-square tests. Continuous variables were compared with categorical variables by analysis of variance and F and t tests.

Dr. Garetz is Associate Professor, Department of Psychiatry, University of Minnesota School of Medicine, Minneapolis, Minn. 55455.

RESULTS

Ninety-one percent (N=184) of the psychiatrists polled responded. Their mean age was 45.7, with a range of 27–80 years. Nearly two-thirds of the respondents worked in the Twin City metropolitan area; the other third worked in smaller communities. Forty percent of the sample were working primarily in public settings, with the remainder in part- or full-time private practice. Less than 4 percent of the sample reported a special interest in geriatric psychiatry, and the proportion of older patients seen in the entire sample was 10.9 percent of the total case load. Table 1 presents these and other descriptive data related to preferred mode of treatment, area of interest, and type of practice.

Four specific constellations of variables were analyzed for significant relationships; the results of these analyses will be presented in the following sections.

There were several significant relationships involving psychiatrists' ages. The mean age of the 20 psychiatrists who more often made the diagnosis of anxiety in older patients (64.5 years) was higher than the mean age of the 77 psychiatrists who more often diagnosed organic brain syndrome (43.0 years) ($p < .001$, t test). Younger psychiatrists more often thought evaluation and somatic treatment were indicated in aged patients, whereas older psychiatrists more often advocated more comprehensive treatment, including psychotherapy ($p < .06$). Psychiatrists who found older patients more interesting (N=115) were significantly older on the average than those who found these patients less interesting (N=38) (means of 46.75 and 41.34 years, $p < .05$, t test). Also, the 121 psychiatrists who found older patients more gratifying were older than the 31 who found them less so (means of 47.21 and 36.61 years, $p < .001$, t test).

Area of Special Interest

The responses to this question were coded into the five categories listed in table 1, and the following relationships were found to be significant: 1) General psychia-

TABLE 1
Data on the Practices of Psychiatrists Surveyed (N = 184)

Item	Number	Percent
Area of interest		
General	123	66.84
Child-adolescent	18	9.78
Psychoanalytic	19	10.32
Geriatric	7	3.81
Social and community	11	5.98
Other	6	3.27
Type of practice*		
Primarily inpatient	68	37.16
Primarily outpatient	48	26.23
Equal combination of both	67	36.61
Primarily private	85	46.70
Primarily public	74	40.65
Equal combination of both	23	12.65
Geographical area*		
Metropolitan area	109	62.64
Small community	37	21.26
Rural area	28	16.10

*Numbers in these categories do not total 184 due to lack of responses on questionnaires. Corresponding percents are based on the number of psychiatrists who responded and not the total sample of 184.

trists saw a higher proportion of older patients (13.78 percent) than did either community psychiatrists (8.45 percent) or psychoanalytic psychotherapists (5.68 percent) ($p < .05$ and $p < .01$, respectively, t tests). 2) Overall chi-square value comparing area of special interest and diagnosis was significant ($p < .001$). 3) Overall chi-square comparing area of special interest in psychiatry with degree of interest in older patients was also significant ($p < .05$). Specifically, general psychiatrists reported a greater degree of interest in older patients than community and outpatient psychiatrists and psychoanalytic psychotherapists ($p < .05$).

Most Frequent Diagnoses Reported

The design of the questionnaire provided three blank spaces for respondents to fill in the most frequently seen diagnoses in older people in their practice. Some of the subjects filled in all three, some two, and others only one of the spaces.

The diagnosis most often listed first by the psychiatrists in the sample was depression: 92 respondents listed this first on the questionnaire. Organic brain syndrome was listed first by 44 psychiatrists, making this diagnosis second in frequency. Addictive disorders, anxiety neurosis, and chronic schizophrenia were all mentioned first with approximately equal frequencies that were considerably less than those for depression and organic brain syndrome. When the data were analyzed from another perspective—i.e., the total number of times a particular diagnosis was mentioned—depression was the most frequent (mentioned a total of 151 times), followed by organic brain syndrome (mentioned 143 times), chronic schizophrenia (31 times), addictive disorders (20 times), and anxiety neurosis (15 times).

Psychiatrists' Ages

There was a significant correlation for the entire sample between age of the psychiatrists and percentage of older patients seen ($r = .146$, $p < .05$). When the sample was broken down into various subsamples according to mode of practice or special area of interest (see table 1), most of the correlations were not significant. However, age was positively correlated with number of older patients seen for psychiatrists doing primarily inpatient work ($r = .243$), those working in public settings ($r = .236$), and those who listed geriatrics as a special area of interest ($r = .612$) ($p \leq .05$ for the first two comparisons, no test of significance possible for the last comparison because of small size of subgroup).

Mode of Practice

A comparison was made between mode of treatment (inpatient/outpatient, private/public, rural/urban) and other variables. The following significant relationships were found: 1) Psychiatrists primarily involved in inpatient work saw a higher percentage of older patients than those primarily involved in outpatient work (13.31 percent versus 7.01 percent, $p < .001$, t test). 2) Psychiatrists working in small towns saw a higher percentage of older patients than did psychiatrists working in the metropolitan area ($.05 < p < .1$). 3) Psychiatrists who worked primarily with outpatients favored more comprehensive treatment for the aged than did psychiatrists who worked with inpatients; psychiatrists who worked with inpatients more often saw their preferred role as evaluation or somatic treatment ($p < .001$). 4) Outpatient psychiatrists as compared to inpatient psychiatrists favored the diagnosis of depression over the diagnosis of organic brain syndrome ($p < .001$, chi-square test).

Other Relationships

There were several other significant relationships between the variables I studied. First, psychiatrists who favored treating older patients saw a higher percentage of older patients than those who saw their role as purely evaluative ($p < .02$). Also, the type of treatment favored for older patients was related to optimism about treatment outcome ($p < .001$); and the types of diagnoses more often reported were related to the kind of treatment favored. Specifically, psychiatrists who tended to report more anxiety neurosis favored more comprehensive treatment and those who reported relatively more organic brain syndromes favored evaluation and somatic treatment ($p < .01$).

CONCLUSIONS

As with all data collected in questionnaire studies, one must interpret the findings of this study cautiously. Further, certain imponderables loom large, such as the following: Is the percentage of patients reported actually the percentage seen? When diagnoses are mentioned, are they accurate statements of diagnoses made or do they

represent attitudes of the psychiatrists? When subjects report their degree of optimism, interest, or gratification from older patients, are they operating under a halo effect because they know that the author is interested in geriatric research?

Despite the inherent limitations or imponderables of questionnaire research, I offer the following conclusions:

Depression is the most frequent diagnosis seen in the aged, closely followed by organic brain syndrome. Anxiety neurosis, addictive disorders, and chronic schizophrenia are next, in about equal frequency.

Age is weakly related to the degree of involvement with older patients for inpatient psychiatrists, public psychiatrists, and geriatric psychiatrists. Also, older psychiatrists are more likely to make the diagnosis of anxiety neurosis (a more treatable condition) than are younger psychiatrists; also, younger psychiatrists prefer less involvement (evaluation or somatic treatments) than do older psychiatrists, who favor combinations of treatment including psychotherapy.

General psychiatrists are more interested in older patients than those psychiatrists who have an outpatient orientation (psychoanalytic psychotherapists and community psychiatrists). Also, rural psychiatrists see more older patients than do their colleagues in metropolitan areas. Those psychiatrists who do exclusively outpatient work see fewer older patients but prefer more comprehensive treatment (including psychotherapy).

Finally, for the overall sample, there was a positive relationship among the factors of optimism about treatment outcome, making diagnoses with more favorable prognoses, and preferring treatment rather than mere evaluation for older patients.

Saliva Lithium Levels: Clinical Applications

BY CARLOS NEU, M.D., ALBERTO DIMASCIO, PH.D., AND DAVID WILLIAMS, PH.D.

The authors note that despite a few reports in the literature indicating that saliva lithium levels could adequately replace serum determinations in monitoring patients being treated with lithium salts, this procedure has not received much clinical application. A study of 20 patients investigated correlations between serum and mixed saliva and parotid fluid lithium levels and documented the reliability of this procedure. The authors suggest that an individual patient's ratio of serum to saliva concentrations should be calculated and used as a constant in the determinations. Patients can collect saliva samples and send them to the laboratory prior to their visits, decreasing the facility's sample collection costs and the patients' inconvenience and discomfort.

LITHIUM CARBONATE IS A psychotropic drug that has received considerable attention from psychopharmacologists in this country and in other parts of the world (1, 2). The use of lithium carbonate in the treatment of the manic phase of bipolar affective disorders and in the prophylaxis of certain types of depression is well established (3–5). When patients are being treated with lithium salts, close supervision is maintained on the serum level of this electrolyte. This is essential because the amount of lithium required to achieve a therapeutic response depends on the concentration of the ion in the serum—which in turn reflects its distribution throughout the body (6)—rather than on the actual amount given per day.

It is recommended that serum levels be obtained frequently (as often as every 48 hours during the first week) at the outset of lithium therapy in order to titrate the drug administration to therapeutic levels (between 1.0 and 1.4 mEq/liter) and to avoid exceeding 1.5 mEq/liter (near toxic level). Serious toxic reactions can develop as a result of poor monitoring (7–9). Once the levels have stabilized, the right oral dose has been found, and the patient exhibits a beneficial response, the serum level need not be monitored more than once every four to six weeks unless toxicity or psychological decompensation occurs.

Drs. Neu and DiMascio are with Boston State Hospital, 591 Morton St., Boston, Mass. 02124, where Dr. Neu is Staff and Research Psychiatrist and Dr. DiMascio is Director of Research. Dr. DiMascio is also Director of Psychopharmacology, Department of Mental Health, Commonwealth of Massachusetts. Dr. Williams is Research Chemist, Abcor, Inc., Cambridge, Mass. Address reprint requests to Dr. Neu.

The authors would like to thank Mr. John Carpenter of Myerson Laboratories for processing the saliva and blood samples in this study.

A series of serum determinations requires repeated drawing of blood samples. An alternate method of determining lithium level is to assay salivary gland secretions. The clinical application of saliva lithium levels has not found a place in the medical armamentarium, although a few investigators have studied lithium in the secretions of the salivary glands and have found high correlations between saliva and serum lithium levels. In 1903, Good (10) used lithium salts to gain a better understanding of the secretions of the parotid and submaxillary glands. He reported that lithium was secreted in saliva at a higher concentration than is found in plasma. In 1969, Spring and Spirtes (11) and Shopsin and associates (12) published further findings on lithium as a saliva and serum electrolyte. Both groups of researchers reported that the concentration of lithium in saliva was several times higher than the level found in serum. Saliva determination spares the patient frequent venous punctures, lessens the cost of collection equipment (syringes, needles, sterile gauze, etc.), and eliminates the need for the patient to travel to a physician or laboratory to have blood drawn.

Review of the literature we have cited suggests that serum lithium levels could be adequately and reliably replaced by saliva lithium levels, with the advantages stated previously. Based on this information, we did a preliminary study that compared mixed saliva, parotid fluid, and serum lithium concentration in one patient on lithium therapy. Subsequently, we collected data on 19 patients receiving lithium carbonate; in 6 patients the determinations were repeated. Our purpose was to find the correlations between the concentrations of lithium carbonate in the three fluids.

METHOD

Subjects and Procedure

The first patient we studied had been taking lithium carbonate (1250 mg per day) for two years and had been free of symptoms for one year. On the day of the assay, the patient was asked to refrain from taking the morning dose of lithium until he came to the laboratory. He had ingested his last dose of lithium (500 mg) the previous night, approximately 12 hours before the first samples of blood and saliva were taken. Lithium, sodium, potassium, and chloride levels were measured in serum, mixed saliva, and parotid fluid five times during the day: just prior to a 750-mg dose of lithium and 75, 180, 260, and 385 minutes later. The saliva flow rate was also measured at each of these times.

In the second phase of our investigation, the subjects were the first 19 patients on lithium therapy (both in- and outpatients) who came to the chemical analytic laboratory at Boston State Hospital to have their regular serum lithium assay done. In all cases, the subjects took their last dose of lithium carbonate 8 to 10 hours prior to the time of sample collection. Diagnoses and severity of symptoms were not taken into consideration. In addition to having blood samples drawn, these subjects were asked to provide parotid fluid and mixed saliva samples.

Collection and Analysis of Samples

Sample collection. Blood samples of 10 ml were collected without anticoagulant and allowed to clot at room temperature. The serum was separated from the cells within one hour of collection.

Each subject was requested to chew Parafilm M (American Can Co.) for one minute or more, swallowing several times. Then, a saliva rejector with a rubber bulb was used to collect 2 ml of whole saliva. Next, the subject was given a sour lemon candy, a parotid fluid collecting cup was put in place, and 1 ml of parotid fluid was collected into a test tube from the tube attached to the parotid cup (13).

These samples were refrigerated at 4 C overnight and centrifuged. After refrigeration, salivary mucin was readily removed by this method in all but a few samples. In these few instances, mucin was coagulated by heating it briefly in a boiling water bath and then separating it by centrifugation.

Electrolyte analysis. Sodium and potassium were assayed by emission flame photometry and chloride was determined colormetrically (chloride was determined only for the one patient in the preliminary study).

Lithium was estimated by emission flame photometry. Lithium standards for determination of lithium levels in serum were prepared in pooled, normal, lithium-free serum. For saliva and parotid fluid levels, aqueous lithium standards were prepared containing 60 mEq/liter of sodium and 20 mEq/liter of potassium.

RESULTS

Preliminary Study

The analyses of electrolytes in the mixed saliva, parotid fluid, and serum for the patient for whom the samples had been taken at five different times indicated rising and falling levels of lithium concentration over time. The concentration of lithium reached the highest level in the collection taken 75 minutes after ingestion of 750 mg of lithium, both in the serum and parotid fluid (1.25 and 3.00 mEq/liter, respectively), while in the mixed saliva, the level was highest three hours after drug ingestion (3.10 mEq/liter). The correlation coefficients for saliva to serum and parotid fluid to serum were identical (Pearson $r=.94$). A near constant ratio was found between serum and saliva or parotid fluid lithium levels, with an average serum to saliva lithium ratio of 2.35 (SD=.17) and a parotid fluid to serum lithium ratio of 2.20 (SD=.20). (The ratios were similar because the parotid fluid and saliva values were similar.) The constancy of the ratio was also similar for both fluids (variabilities of 7.1 percent and 9.0 percent, respectively). These results also indicated no time delay in the appearance of lithium in serum and in mixed saliva.

The correlation coefficients between lithium and potassium, sodium, and chloride in the two salivary fluids were rather low. In saliva, the correlations were .46, .66, and .41 for sodium, potassium, and chloride, respectively; in parotid fluid, the respective correlations were −.40, .67, and .02. This suggests that the lithium ion behaves independently of the changes of electrolyte concentrations in the salivary glands. Correlations for serum lithium and sodium, potassium, and chloride, respectively, were .80, .89, and .71.

Main Study

Although other electrolytes were measured in the 19 patients studied in this part of our investigation, only lithium levels will be discussed because (as stated previously and confirmed by the low correlations found in this phase of the study), lithium acts independently of the other ions.

The average serum lithium level for all patients was .69 mEq/liter. The averages for saliva and parotid fluid, respectively, were 1.56 and 1.52 mEq/liter. The correlation between the individual parotid fluid and serum lithium levels was .92; for the mixed saliva and serum lithium levels, the correlation was .90. The ratios for saliva to serum lithium and parotid fluid to serum lithium were remarkably similar, with mean ratios of 2.26 (SD=.23) and 2.21 (SD=.20), respectively. The coefficient of variability was 10.2 percent for saliva to serum lithium and 9.0 percent for parotid fluid to serum lithium.

DISCUSSION

Our findings suggest that saliva or parotid fluid lithium levels can be used as reliable indicators in monitoring lithium treatment. High correlations (from .90 to .95) were found between serum and saliva and serum and parotid fluid lithium levels in both phases of the study.

In addition, a highly reproducible constant relationship was noted between the mixed saliva lithium levels and serum level. The average constant was 2.26 ± 10 percent (i.e., saliva lithium divided by 2.26 is equal to serum lithium). Thus the saliva lithium level can be readily converted to the equivalent serum lithium level. The individual ratios of saliva to serum lithium ranged from 1.83 to 2.87, but in the six patients for whom samples were collected and measured twice, the individual scores varied only ± 8.6 percent from the first to the second measurement. Accordingly, we feel that to use saliva most effectively in determining lithium levels, the ratio between saliva and serum lithium levels should be calculated for each individual, and this specific ratio should be used for subsequent determinations for that individual.

The use of saliva lithium determinations has several practical advantages. Patients are spared the discomfort

of repeated venipunctures; the trained technicians required to draw blood are unnecessary because the patient collects the saliva himself; and the need for patients to travel to a laboratory or physician to have blood drawn is eliminated. Saliva can be collected and mailed to a laboratory, and the results can be sent to the doctor prior to the actual visit by the patient. In this way, the drug can be monitored and changes in dosage can be made on the spot. Both acceptance of and ease of treatment with lithium will be facilitated by the use of saliva lithium determinations.

Renal Tubular Function in Patients on Long-Term Lithium Therapy

BY GEOFFREY W. VIOL, M.B., PAUL GROF, M.D., PH.D., AND LESLEY DAIGLE, R.N.

The authors conducted a study in which 10 patients with recurrent affective disorders who responded completely to long-term lithium therapy but who were otherwise unselected were tested for renal tubular concentrating and acidification ability. Despite frequent symptoms of thirst, polyuria, and nocturia, all patients were able to concentrate urine normally and all showed normal renal tubular acidification ability. A significant correlation was found between erythrocyte lithium concentration and maximum urinary osmolality.

IN RECENT YEARS the administration of lithium salts has achieved increasing acceptance in the treatment of affective disorders. Greater awareness of the side effects of this drug has followed. Polyuria and polydypsia were described as side effects in humans in 1968 (1), and examples of a nephrogenic diabetes insipidus-like syndrome have been reported (2–7) in patients with therapeutic levels of plasma lithium.

In rats, polyuria and polydypsia as well as an inability of the kidneys to concentrate urine in response to vasopressin have been described as symptoms of toxicity at lower plasma lithium concentrations (8). At higher lithium levels, oliguric renal failure has occurred (8).

In humans, lithium overdosage has resulted mainly in central nervous system manifestations; renal involvement has been mild and reversible (9). Polyuria and polydypsia, which have occurred in some patients with therapeutic plasma lithium levels, probably have a different explanation. Experimental studies have suggested interference by lithium with the action of vasopressin (10), possibly by inhibition of vasopressin-sensitive adenyl cyclase (11).

The frequency of the diabetes insipidus-like syndrome in patients on lithium therapy has not been determined,

Dr. Viol is Assistant Professor, Department of Medicine, St. Joseph's Hospital and McMaster University, Hamilton, Ont., Canada. Dr. Grof is Associate Professor, Department of Psychiatry, McMaster University, and Director, Affective Disorders Clinic, Hamilton Psychiatric Hospital, Hamilton, Ont., Canada. Ms. Daigle is Head Nurse, Affective Disorders Clinic, Hamilton Psychiatric Hospital. Address reprint requests to Dr. Grof at P.O. Box 585, Hamilton, Ont., Canada.

The authors wish to thank Dr. K. Fritze and Dr. R. Robertson for the lithium assays.

although one study (12) found that 12 percent of 85 patients excreted over 3 liters of urine in 24 hours.

We investigated renal tubular concentrating ability in 10 patients on lithium therapy selected only by criteria of response to treatment. Because of our experience with one patient (4) we also studied renal tubular acidification function in these patients.

PATIENTS

A large sample of patients maintained on long-term lithium therapy at the Affective Disorders Clinic in Hamilton Psychiatric Hospital was subdivided, according to response to prophylaxis, into complete responders, intermediate responders, and failures. The classification was based on psychiatric criteria alone; the presence of possible side effects such as polyuria or polydypsia was not considered. A group of 32 complete responders (13) was recognized; although these patients had a high risk of further episodes of affective disorders, they developed no relapse during a treatment period exceeding 12 months.

Ten women from the group of complete responders, but otherwise unselected, were able to participate in an intensive outpatient investigation of renal function without undue disturbance to their daily routines. They had been treated with lithium for an average of two years and seven months; their mean age was 50.3 years. The average daily dose of lithium carbonate was 1200 mg (range, 900 to 1500 mg).

METHOD

Lithium concentrations in serum and erythrocytes were measured by flame photometry. After separation of serum and erythrocytes by standard centrifugation techniques, 1-ml samples of both were taken, diluted to 100 ml, refrigerated, and later analyzed by flame-photometric method. A correction for trapped serum was made to the erythrocyte values (14).

Urinary osmolality was measured by freezing-point depression and urine pH was measured with a glass electrode.

Renal tubular concentrating ability was tested by measuring maximum urinary osmolality achieved following an 18-hour water fast and 5 units of subcutaneous vasopressin (Parke-Davis). The normal response, defined elsewhere (15), was greater than 700 mOsm/kg.

Renal tubular acidification ability was tested by measuring minimum urinary pH achieved following an oral dose of ammonium chloride (0.1 g/kg in 1 liter of water). The normal response (16) was below 5.40.

RESULTS

Three patients were found to have a significant bacteriuria (colony count over 100,000) and 1 was hypertensive.

Six patients reported increased daytime thirst and polydypsia on lithium therapy, 6 reported nocturia 2 to 5 times nightly, and 6 reported the need for extra nighttime fluids following lithium therapy.

We obtained the following mean measurements for the 10 patients:

1. Plasma lithium concentration at the time of investigation was 0.76 ± 0.12 mEq/liter (range, 0.61 to 0.91).
2. Erythrocyte lithium concentration was 0.38 ± 0.10 mEq/liter (range, 0.22 to 0.52).
3. Maximum urinary osmolality achieved in the 10 patients was 862 ± 88 mOsm/kg.
4. Minimum urinary pH achieved by the lithium-treated patients was 5.11 ± 0.24.

There was a significant relationship between erythrocyte lithium concentration and maximum urinary osmolality ($r = .67$, $p < .05$, by Spearman rank correlation test).

DISCUSSION

More than half of the 10 patients reported subjective disturbances of thirst and micturition but all were able to concentrate urine normally on formal testing. Increased thirst in rats following lithium treatment in the absence of polyuria and dehydration has been reported (17). Another study (18) demonstrated a significant reduction in concentrating ability in 7 of 10 nonpolyuric patients. Study of a larger group of patients will be necessary to define the incidence of subjective disturbances of water metabolism and of renal concentrating ability; this study has been initiated.

We had earlier observed a patient with defective tubular acidification (4); experimental studies have shown defects of tubular acidification in rats given lithium (18), and a transient reduction in titratable acidity in urine in normal subjects given lithium carbonate has been demonstrated (19). However, in the present study all 10 patients showed normal urinary acidification in response to ammonium chloride ingestion.

The significant correlation between maximum urinary osmolality and erythrocyte lithium concentration is a further indication of the importance of erythrocyte lithium as a guide to tissue effects of lithium (20).

New Perspectives in Psychiatry in the Veterans Administration

BY JOSEPH J. BAKER, M.D.

In 1972, the mental health services in the Veterans Administration were reorganized in a manner designed to increase the probability of interdisciplinary collaboration. VA hospitals were urged to form multidisciplinary mental health committees to advise on local programs and practices. This "corporate" approach has led to significant changes in the use of staff and in the physical and psychological environment in some hospitals. While it is too early to evaluate the full impact of the changes on patient care, waiting lists have been reduced and length of hospital stay has decreased.

WITHIN THE PAST FOUR YEARS, there have been numerous changes in the structure and function of psychiatric services in the Central Office of the Veterans Administration and, to a somewhat lesser extent, in its treatment facilities. Although too little time has elapsed to permit final evaluation, impressions thus far have been favorable. This paper will describe these changes and discuss some of the effects they have had.

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Dr. Baker is Director, Mental Health and Behavioral Sciences Service, Veterans Administration Central Office, 810 Vermont Ave., N.W., Washington, D.C. 20420.

First, a word about the internal structure of the VA. A large Department of Medicine and Surgery is responsible for all aspects of patient care and for research, education, and medical administration. The department is centrally directed from Washington, D.C., by a chief medical director and his staff. Within this Central Office, each large professional service has its own staff, director, and professional advisory groups. While the professional services do not control funds or exercise authority over operations, they exert considerable influence because of their responsibility for setting professional and technical standards for both personnel and treatment programs throughout the system. They also provide a visible axis about which various training, recruitment, and research activities rotate.

The Mental Health and Behavioral Sciences Service presides over the work of 84 general hospitals offering psychiatric treatment, 28 psychiatric hospitals, 80 mental hygiene clinics, 48 day treatment centers, 37 day hospitals, 53 drug dependence treatment centers, 69 alcoholism treatment centers, and other specialized facilities for persons who are suffering the effects of mental or emotional disorders. These facilities treated 162,000 inpatients in 1972—20,000 more than were treated in 1967. During the same five-year period, the bed capacity and daily census of psychiatric patients dropped by about 25 percent to its present level of approximately 30,000, and outpatient visits increased from 900,000 to 1.6 mil-

lion (1, 2). It can be seen, then, that the VA has made the same philosophical commitment to short-term hospital treatment, rapid turnover of inpatients, and a vast increase in outpatient resources that the rest of American psychiatry has made. In addition, the VA supports hundreds of hospital-based behavioral research projects and each year trains hundreds of residents in psychiatry and doctoral candidates in psychology.

HISTORY OF THE SERVICE

Prior to 1972, the VA Central Office grouped its resource people into a Psychiatry, Neurology, and Psychology Service, which was headed by a psychiatrist. The responsibilities of this service were almost entirely related to the three named disciplines. While there was a degree of collaboration among them, each tended in practice to serve and relate almost exclusively to its counterpart discipline in the hospitals and clinics. The disciplines of nursing, social work, and rehabilitation medicine were represented in the Central Office and in the field by separate but equal services. While this organizational style was adequate for many aspects of the VA's mission, there was a growing feeling that patient care would be considerably enhanced if professional services were grouped in a way that would improve the probability of collaboration in program development.

As a result, in 1970 a Committee on Mental Health and Behavioral Sciences was appointed in the Central Office. This body was asked to study the VA's total mental health effort and to make recommendations for improvement. Headed by the director of the Psychiatry, Neurology, and Pyschology Service, the core group included an executive secretary, two psychiatrists, two psychologists, two social workers, two psychiatric nurses, one neurologist, one physiatrist, and one chaplain. All were highly knowledgeable individuals whose years of experience included significant work in both the clinical and administrative segments of large health bureaucracies. Each had been thoroughly steeped in the traditions and values of his own profession and was actively involved with his national professional societies.

While there was no naive expectation that change would occur easily, the members of this group were unanimous in their enthusiasm for the task and collaborated closely in studying the VA's total clinical case load, its resources, treatment programs, training and research, and the statutes and regulations governing its operation. Each subject was investigated in depth by individuals or subcommittees, who brought their findings and recommendations to the full committee for elaboration and discussion. It quickly became apparent that changes on a pan-professional scale were being considered and that they would not be brought about by a part-time committee; they would call for an unremitting multidisciplinary effort for years to come. Thus, by natural progression over many months the committee arrived at a recommendation that a permanent new service be established in the Central Office and that it be designed to exert its influence in a way that would carry the weight of all the disciplines involved in providing mental health care.

Early in 1972 the recommendations creating the Mental Health and Behavioral Sciences Service in place of the Psychiatry, Neurology, and Psychology Service were approved. The new service was headed by a psychiatrist and included the psychiatry and psychology components of the old service. Neurology became a separate service. Social work, nursing, and rehabilitation medicine each detailed certain individuals to work as full partners in the new service, and the directors of these companion services formed an advisory council to the director of the Mental Health and Behavioral Sciences Service.

ORGANIZATION AND ACTIVITIES OF THE SERVICE

In a new departure, the service was organized into divisions that were subject to multidisciplinary input instead of being the domain of a single discipline. Hence, from the outset the service dealt with its everyday work load in a distinctly different way. Problems relating to treatment programs were referred to the Division of Treatment Services, which included representatives from psychiatry, psychology, social work, nursing, and rehabilitation medicine. (The Program Development Division and the Division of Alcohol and Drug Dependence are similarly multidisciplinary in input.)

Operating in this collective or corporate way, the service was able to focus attention on certain problem areas that had been recognized by individual workers for some time. For example, the physical surroundings in the treatment areas of some hospitals needed much improvement if they were to enhance treatment rather than detract from it. The accomplishments of hospitals that had shown creativity in the use of colors and textures and general improvement of the living space for patients were highlighted in meetings, talks, and by a VA-produced film. In this way, the service was able to stimulate all mental health personnel to look for ways to improve the physical environment at their own facilities.

In a somewhat different way, the service became involved in the VA's attempt to improve the psychological environment in all its hospitals and clinics. Many Viet Nam veterans were outspokenly critical of the VA, which led the Administrator of Veterans Affairs to hold hearings in several VA centers around the country in 1970 and 1971. In these hearings, young veteran patients were encouraged to air their grievances about the system and tell what they thought should be changed. While most of the veterans seemed satisfied with the results of their treatment, there were criticisms related to impersonal and uncaring attitudes in VA hospitals and to regulations and programs that seemed to be geared to an older and different veteran population. As a partial response to this, a long-range program was begun to sensitize hospital workers to the emotional and human needs of people seeking help.

A centralized training course in group and individual

effectiveness that was originally designed for workers in admission areas of VA hospitals was launched in 1972 under the guidance of the Mental Health and Behavioral Sciences Service. The people who went through this training became much more aware of the importance of a caring attitude and the ways in which the presence or absence of this attitude showed in their verbal and nonverbal exchanges with patients. These individuals became trainers of their colleagues when they returned to their hospitals.

The service was also able to focus attention on needed changes in regulations. For example, statutory requirements had for years made it impossible for a veteran with a non-service-connected disability to receive outpatient treatment unless he had first been an inpatient. Whatever its intent, the effect of this regulation was to hospitalize many persons for no other purpose than to make them eligible for outpatient care. The language of a statute that dealt with sharing of VA facilities permitted sharing contracts with community hospitals and medical schools but neglected to mention mental health centers or other freestanding nonhospital mental health facilities. In both of these instances, the new service, because of its multidisciplinary character, was able to mobilize professional opinion and get necessary legislative remedies proposed.

It was recognized that the Mental Health and Behavioral Sciences Service would need to be quite flexible in relating to VA hospitals and clinics. Most of these treatment facilities had been in operation for years and were providing a level of care that was at least comparable to that in other public facilities. For this reason, there was no emergency that required them to reorganize, as the Central Office had done. Instead, the staff of each hospital was encouraged to examine the treatment program in its own setting to see if the program might be made more effective.

At the same time, however, the newly organized Mental Health and Behavioral Sciences Service in the Central Office deliberately began using several techniques designed to demonstrate the effectiveness of the multidisciplinary approach. One of these techniques was the routine use of the multidisciplinary team to make station visits and evaluate mental health programs. Another was the career development workshop for selected mental health professionals from VA hospitals and clinics. Each of these workshops brought to the Central Office a different mixed group of 12 to 15 chiefs of the disciplines related to mental health for three days of informal orientation by the Central Office staff. On a much larger scale, during the last two years there have been three large regional meetings, each of which involved personnel from as many as 35 or 40 hospitals, including chiefs of staff and the chiefs of psychiatry, psychology, rehabilitation medicine, social service, nursing service, chaplaincy, and volunteer services. Participants at these meetings were briefed on multidisciplinary concepts but, more importantly, they spent most of the three days in small group discussions. Each individual met in groups that were multidisciplinary (first with professionals from different hospitals and then with colleagues from his own hospital) and also in groups of single disciplines to discuss the implications of the multidisciplinary approach to institutional mental health programs.

SPREAD EFFECT OF THE MULTIDISCIPLINARY APPROACH

Each of these techniques—the team visit, the career development workshop, and the multidisciplinary conference—has had the effect of modeling the multidisciplinary approach. As a result, many hospitals have established mental health committees composed of chiefs of mental-health-related services. Each committee has tried to define its hospital's mental health mission, its resources, the characteristics of its patient load, and its treatment programs. In most cases, the leadership of the committee has been assigned to the chief of psychiatry, although in some committees, by consensus, this role has fallen to other professionals.

In the hospitals that have gone through this exercise, there has been almost unanimous enthusiasm for the group process and the novel and stimulating experience of being invited to make corporate recommendations that might affect all aspects of the hospital's mental health program. In completing this phase of their mission, committees have been able to agree on various things that might improve services.

Problems of Implementation

Attempts to implement the ideas of the newly created committees I have described have not always been harmonious. Many recommendations have involved new, expanded professional roles and the loosening up of the process of clinical decision making. This might take the form of a recommendation that nonphysicians manage wards, make basic decisions about hospital admission, or coordinate the work of a clinical staff. Each such change involves realignment of roles and delegation of authority that has traditionally been vested in the physician.

Other recommendations have related to team function and have anticipated that team members would help determine team goals and priorities. Where this kind of operation has not previously existed, it has sometimes been difficult to start. The personalities of the team members are crucial. Not surprisingly, a psychiatrist accustomed to having "his" staff carry out his decisions about patients or about the operation of the ward does not easily accept a role that seemingly limits his executive function. Other professionals have equally compelling prerogatives and idealized roles that need to be worked through. Factors like these must be faced and dealt with realistically by the team in order for it to function effectively.

Another variable has been the organizational orientation of the departments of psychiatry in the 89 medical schools affiliated with our hospitals. Many of these schools have adopted a multidisciplinary mode of organization fairly compatible with our own. Other departments, more traditional in their orientation, espouse a

teaching and treatment model dominated rather completely by psychiatry. We have tried to accommodate to both philosophies.

COMMENT

In view of the variety of personal and institutional influences at work, it is perhaps surprising that so many hospitals have been able to make perceptible improvements in their programs by the multidisciplinary approach. Yet it is clear that significant beginnings have been made and that they have not been nearly so disruptive as many professionals feared they might be. In the process, mental health staffs have begun for the first time to show a corporate awareness and concern about long-standing mental health problems facing their hospitals. Furthermore, they have attempted to do something about these problems.

It is too early to evaluate the full impact of these changes on patient care. It is possible, however, to point to some of the effects, such as the abolishment of long-standing lists of patients waiting for admission and treatment and reductions of patient census, and to infer from these effects that patients have been helped. Living areas have been redecorated and rearranged in ways calculated to enhance the patient's comfort, dignity, and self-esteem, and from this it can be inferred that the patient is more likely to improve than he would be in a setting that is ugly and crowded. One can find increasing numbers of VA hospitals where the whole range of mental health treatment services is under the continuous scrutiny of a local multidisciplinary task force, by one title or another, and infer that the many encounters patients have are more likely to be therapeutic because the local staff has contrived ways to make them so.

Although we base our programs on these inferences and others like them, they contain many areas that call for further critical study and evaluation. Psychiatry has had a major part in fostering the multidisciplinary concept and making it work. At this point in history, however, it seems clear that an increasing amount of the energy and time of psychiatrists in leadership roles will be consumed in eliciting cooperative efforts from other people. This is a demanding and often frustrating task, and it is not surprising that some perfectly capable psychiatrists prefer to concentrate on patients and leave team management and coordinating functions to others.

The multidisciplinary team approach is not new, but its promotion in a system the size of the VA has been a novel undertaking. The VA health system provides an ideal laboratory to test this approach because of its size, the great variety of its resources, and the high level of professionalism of its personnel. At this point, we make only modest claims about its superior effectiveness in patient care. At the very least, however, this approach creates an open system that involves everyone in establishing and attaining goals both in the ward and in the hospital as a whole. While this in itself does not make patients better, it seems to us that it creates a posture and setting in which the possibility of patient improvement is greatly enhanced.

Effects of 5-Hydroxytryptophan on Fragmentation of REM Sleep in Alcoholics

BY VINCENT P. ZARCONE, JR., M.D., AND ERIC HODDES, M.A.

The authors studied the effects of oral loading with 5-HTP on REM fragmentation in a group of alcoholics who were abstinent following acute ethanol withdrawal. Decreased fragmentation was found in the majority of subjects, and those subjects with low baseline REM efficiency (i.e., greater fragmentation) showed more improvement from the drug than did subjects who were less impaired initially. The authors suggest that there is an organic decrement of serotonin during ethanol withdrawal which is partially reversed by 5-HTP loading.

IT APPEARS THAT 5-hydroxytryptophan (5-HTP) could be effective in the treatment of the sleep disorders of alcoholics because of two interrelated factors: the substrate relationship of 5-HTP to serotonin (5-HT) and, relatedly, the considerable disruption of serotonergic sleep regulation that is found in alcoholics (even those who have been abstinent for many weeks). This study compares the administration of 5-HTP to placebo in a group of 12 alcoholics who were abstinent from alcohol following acute ethanol withdrawal.

The role of serotonin in REM and non-REM sleep has been most extensively described by Jouvet (1), who contended that serotonin is a necessary component in the regulation of REM sleep. Serotonin is also necessary for the initiation of non-REM sleep and acts as a primer for the maintenance of REM sleep.

It has been suggested that alcohol ingestion creates an imbalance in serotonergic sleep mechanisms in alcoholics. During drinking periods, alcohol decreases REM sleep. During withdrawal from alcohol, REM sleep is increased but remains fragmented for many days (2). Non-REM slow-wave sleep is also affected by ingestion of alcohol. Terminal sleep during recovery from alcoholic psychosis has been found to be predominantly slow-wave sleep (3), and defects in slow-wave sleep after one to two years of abstinence have been found in alcoholics (4).

We hypothesize that if serotonergic regulation is abnormal in alcoholics, as suggested by the studies cited previously, then loading the system with 5-HTP may help to restore normal sleep. Evidence for the efficacy of 5-HTP in correcting 5-HT imbalance comes from Dement and associates (5). These authors found that 5-HTP abolishes waking ponto-geniculate-occipital spikes, decreases irritability, hallucinations, and abnormal drive-oriented behaviors, and leads to normalized sleep in cats depleted of serotonin by *p*-chlorophenylalanine. Moreover, it has been found that 5-HTP loading leads to normalized sleep after a serotonin-depleted midline raphe nucleus lesion (6, 7).

Alcohol withdrawal syndromes and subsequent drinking bouts may be manifestations of an inability of the serotonergic raphe system to maintain a tonic REM sleep state in which modulation of limbic system regulation of drive-oriented behavior occurs. Admittedly, this hypothesis is highly speculative. However, if it is at all accurate, administration of 5-HTP should decrease abnormalities of REM sleep in alcoholic patients who have sleep abnormalities that persist during abstinence.

SUBJECTS AND METHOD

The design of the study conformed to a 14-night sedative-effectiveness protocol frequently used in sleep research laboratories. However, several additional measures were employed due to our unusual clinical population and the nature of the drug compound.

The subjects were 12 men whose ages ranged from 25 to 52 years (mean=40.7). The number of years these subjects had been drinking ranged from 3 to 34, with a mean of 14.3 years. The subjects had been abstinent for 23 to 133 days before the study began.

The subjects were housed in 24-hour-a-day inpatient wards where they were constantly observed in order to prevent drinking. During the study, each subject slept in a sound- and light-attenuated temperature-controlled room for 14 consecutive nights. All subjects maintained a total dark time in bed of 8 hours (from 10:30 p.m. to 6:30 a.m.).

The first night of the study was used to acclimate the subjects to the laboratory surroundings. Nights 2 to 6 were baseline (placebo) nights, nights 7 to 11 were drug nights, and nights 12 to 14 were recovery (placebo) nights. Each night the subjects received one capsule at 7:30 p.m. and two capsules at 9:00 p.m. On drug nights, each capsule contained 100 mg of 5-HTP; on placebo nights, the capsules contained lactose. Throughout the study, subjects were given bedtime and morning questionnaires to assess the quality of sleep and possible drug side effects. One subject reported abdominal pains on one placebo and one drug night.

Dr. Zarcone is Senior Attending Physician, Department of Psychiatry, Stanford University, Stanford, Calif. 94305. Mr. Hoddes is with the Department of Psychology, University of Colorado, Boulder, Colo.

This research was supported by Veterans Administration research funds and grant AA-00498 from the National Institute of Alcohol Abuse and Alcoholism.

Urine samples were collected from 8 of the 12 subjects following selected drug and placebo nights to ensure that 5-HTP was actually absorbed and metabolized by the body through the oxidating pathway to 5-hydroxyindoleacetic acid (5-HIAA). In each subject, there was a significant increase in excretion of 5-HIAA following drug nights compared to placebo nights ($p=.04$, binomial test).

Each night electrodes were placed on the face, scalp, and chin of each subject according to the standardized sleep montage, and sleep patterns were monitored by polygraphs. The sleep recordings were scored in 30-second epochs by technicians unaware of the experimental manipulations according to the criteria of the standardized sleep scoring manual (8).

RESULTS

Individual and overall means on the conventional sleep variables were calculated and submitted to a matched-sample t test (two-tailed) to compare baseline, drug, and recovery conditions (see table 1). No consistent differences were found at the 95 percent level of confidence for differences between baseline and recovery compared to the drug condition. There was an increase in stage 2 sleep and a decrease in stage 1 sleep in drug periods compared with baseline periods. These small changes persisted into the recovery period.

Although these results suggest that differences were slight for our group of subjects as a whole, we did find obvious drug effects in our subjects on the variable of REM efficiency.

REM efficiency is expressed as a percentage and is calculated by dividing the number of actual minutes of REM sleep by the total number of minutes in the REM periods. (Note that REM periods are defined as any two consecutive epochs of REM sleep separated by 25 minutes or less of other stages.) REM efficiency reflects the degree of REM period fragmentation—lower REM efficiency corresponds to greater REM period fragmentation. Based on normally occurring interruptions of REM sleep, a REM efficiency greater than 90 percent would indicate relatively stable REM periods.

We were particularly interested in those alcoholics with disturbed REM sleep, and we therefore paid close attention to the baseline REM efficiency values of our subjects. We found that 9 of the 12 subjects had REM efficiencies of less than 90 percent. They therefore constituted a suitable sample to use in investigating the effects of 5-HTP in already REM-disturbed subjects.

We submitted the results from these 9 subjects and from the 3 subjects with REM efficiencies greater than 90 percent to matched-sample t tests that compared administration of 5-HTP to baseline and recovery conditions. The results of these tests, shown in table 2, clearly indicate that 5-HTP significantly increased the REM efficiency of the subjects with impaired REM sleep (group 1 in table 2). On the other hand, the 3 subjects who already had high REM efficiencies during baseline (group 2) showed decreased REM efficiencies on the drug, possibly indicating a ceiling effect.

An a priori assumption was made regarding the efficacy of 5-HTP in already REM-disrupted alcoholics after 6 subjects (those designated A–D, J, and K in table 2) had been tested. These results were described at the Serotonin Conference, Palo Alto, Calif., in 1972 (9). After the conference, we tested 6 more of the 12 alcoholic subjects, 5 of whom had basal REM efficiencies of less than 90 percent. We found that REM efficiencies of these 5 subjects improved significantly with 5-HTP ($p \leq .05$). When we pooled the data from the postconference group with that of the other 6 alcoholics, identical or higher lev-

TABLE 1

Comparison of Mean Sleep Variable Data for 12 Alcoholics Before, During, and After Administration of 5-HTP

Item	Condition					
	Baseline		Drug		Recovery	
	Mean	SD	Mean	SD	Mean	SD
Time spent in each stage of sleep (in percents)						
Stage 1*	17.8	4.2	14.3	3.8	14.4	3.8
Stage 2**	45.7	5.1	48.4	5.3	48.5	3.8
Stage 3	9.0	3.4	10.0	2.9	10.3	2.9
Stage 4	5.2	1.8	3.3	2.0	2.9	1.6
REM stage	22.3	4.1	22.7	4.0	22.7	5.4
Other variables (in minutes)						
Sleep latency	22.7	12.7	23.8	13.2	27.6	17.1
Wake time after sleep onset	38.6	19.4	34.4	16.5	39.7	15.6

*Baseline significantly greater than drug ($p<.05$) and recovery ($p<.01$) periods.

**Baseline significantly less than drug and recovery periods (in both cases, $p<.01$).

TABLE 2

Mean REM Efficiencies of 12 Alcoholic Subjects Before, During, and After Administration of 5-HTP, in Percents

Subject*	Condition		
	Baseline	Drug	Recovery
Group 1**			
A	67.6	79.5	72.1
B	76.4	78.4	74.7
C	56.4	61.1	57.2
D	66.9	70.4	66.2

F	69.9	83.9	80.7
G	77.1	84.3	83.2
H	68.4	72.8	73.8
I	62.7	70.8	69.9
Group 2			
J	94.4	86.4	85.0
K	97.2	95.5	91.2
L	95.0	90.5	95.1

*Subjects with baseline REM efficiencies below 90 percent are in group 1; those with baseline REM efficiencies above 90 percent are in group 2.

**For group 1, REM efficiency was significantly greater in the drug condition than in baseline ($p \leq .01$) or recovery ($p \leq .05$).

els of significance were found, as can be seen in table 2.

Unfortunately, two subjects (designated as F and G in table 2) disobeyed hospital rules and consumed approximately two quarts of 100 proof ethanol beverage during two days following the baseline recordings. The sleep variables from these subjects resembled baseline values only after two subsequent recording nights. Administration of 5-HTP began the third night after the drinking spree. Given the nature of ethanol withdrawal, the propensity for a lowered REM efficiency in these subjects was very great. Nevertheless, they also demonstrated increased REM efficiency during drug administration.

DISCUSSION

We believe that our findings are consistent with Jouvet's hypothesis that 5-HT is a neurotransmitter which is important for the priming of REM sleep (1). We assume that there may be abnormal regulation of sleep by serotonergic neurons in most alcoholic subjects, which persists during abstinence. This abnormality is partially corrected by loading the system with 5-HTP. While 5-HTP may not act directly to increase the total amount of REM sleep, it may decrease fragmentation within REM periods, thus allowing more normal non-REM/REM cycling and more stabilized REM sleep.

Finally, even though we were impressed with the increase in REM efficiency in the two subjects who went on a short drinking binge, we believe that more research is required to determine whether larger doses of 5-HTP early in withdrawal will reduce REM fragmentation, decrease wake time after sleep onset, decrease stage changes, decrease stage 1 (transition sleep), and increase stage 2 sleep. Another question of interest is whether improved sleep during abstinence will lead to less drinking.

Reasoned Discourse or a Holy War: Postscript to a Report on ECT

BY FRED H. FRANKEL, M.B.CH.B., D.P.M.

The author points out that both favorable and unfavorable opinions regarding the value of electroconvulsive therapy have become entrenched in the absence of adequate data. These opinions are discussed in relation to the training, experience, and personal orientation of the psychiatrist. The inability of some psychiatrists to tolerate uncertainty is held responsible for their denial of the validity of alternative methods of treatment. The author recommends that psychiatrists tolerate a certain amount of ambiguity and uncertainty: postponing closure may lead to the conclusion that treatment styles (including use of psychotherapy and ECT) are not mutually exclusive.

FOLLOWING THE OBSERVATION that convulsive seizures were at times beneficial in psychiatric illness, Cerletti and Bini (1) in 1938 first used electroconvulsive therapy (ECT) as a means of producing them. The treatment, which is usually repeated on alternate days for some weeks, involves the administration of an electric current (70 to 150 volts) to the brain for .1 to .6 second through electrodes placed over the temples. The procedure has been modified and improved over the years to include the use of general anesthesia and muscle-relaxing drugs, which have made it a relatively safe procedure, with the risk not exceeding that generally encountered with brief anesthesia.

With little but their observations in clinical practice to guide them, psychiatrists have developed different methods of administering ECT, ranging from a maximum number of 8 to 12 treatments over a period of a month to several times that number for many months. Similarly, the selection of ECT as a treatment method varies, with some psychiatrists rarely if ever choosing it and others choosing it fairly consistently. The relationship of the latter group to those who favor the psychotherapeutic approach in treatment captures the essence of the struggle for identity within the psychiatric profession. A consequence has been the righteous indignation of those who virtually never recommend it, offset by a vehement defense by many of those who do.

With the growth of consumer interest and involvement in health care, which had prompted numerous questions about treatment in Massachusetts and elsewhere (especially methods of administering ECT), the Task Force to Study and Recommend Standards for the Administration of ECT in Massachusetts came into existence in January 1972 at the request of Milton Greenblatt, M.D., then Commissioner of Mental Health. The task force of 11 members reviewed the literature for reports of current practice and especially for research data and studied attitudes toward ECT and the methods of administering it from the responses to questionnaires mailed to about 650 psychiatrists and psychiatrists-in-training in Massachusetts. It then attempted to integrate those findings with the opinions of the members of the task force, which included a majority of psychiatrists who use ECT, a child psychiatrist, and others whose major interests were teaching, research, administration, and community mental health.

The task force report (2), which was published early in 1973, included a statement of the purpose of the report, namely to recommend flexible guidelines for the administration of ECT—not to offer rigid requirements. The report drew attention to the dearth of research data, to the small number of respondents (66 of the 650), to the absence of any demonstrable adverse effects following the moderate use of ECT, and to the great need for long-term comparative studies of the effectiveness of different treatment methods in psychiatry. It recommended criteria for selection and methods of procedure; it encouraged further dialogue, study, and publication of the results of using ECT differently; and it called for official statements on ECT by professional bodies of national stature.

In essence, and largely from the accumulated experience of psychiatry, the task force concluded that enough information was available for ECT to be recognized as a necessary and beneficial aspect of psychiatric treatment. It found that there was considerable agreement on the effectiveness of ECT in the treatment of the depressed phase of manic-depressive illness, especially in mid-life or among the elderly, and on the ineffectiveness of ECT in the treatment of character disorders (which may be understood as the root of long-standing maladaptive lifestyles). The members were in agreement that there was no established usefulness in the administration of ECT to children who have not yet reached puberty, and with a struggle, consensus was achieved by the members regarding the use of ECT in depressions considered reactive to life situations. Agreement was also reached on the number of treatments generally considered effective. However, views were *not* unanimous regarding the use of ECT in the treatment of schizophrenia.

Dr. Frankel is Assistant Professor of Psychiatry, Harvard Medical School, and Psychiatrist, Beth Israel Hospital, 330 Brookline Ave., Boston, Mass. 02215.

CONTRASTING VIEWS ON ECT

This article, which describes only my own views, addresses areas where unanimity was not achieved and where consensus barely survives. From the responses to the questionnaires, from the deliberations of the task force, from attitudes rapidly uncovered in discussions on ECT, and from events known to have occurred since the publication of the task force report, the prevalence of contradictory opinions regarding these aspects of ECT is inescapable. What is equally apparent is the certainty with which such contradictory viewpoints are defended and the determination with which opposite opinions are dismissed.

Ruling out the extremists on either side, who are vocal but do not constitute a majority (including the occasional psychiatrist whose excessive use of ECT raises several questions, including moral ones), we are still left with a large number of moderate persons whose behavior is proof of their inability or unwillingness to hear both sides of the problem with equal openness. The responses to the Massachusetts questionnaire came mainly from psychiatrists who use ECT or refer patients for it. From our knowledge of the types of practice that prevail in the state, it was concluded that the vast majority of those who did not respond had insufficient knowledge of or exposure to ECT, were unable to support their unfavorable attitudes, or were uninterested.

Although regarded by many psychiatrists and mental health professionals as a balanced and realistic appraisal of the status of ECT, the report (referred to in some quarters as the Massachusetts Guidelines) has been quoted by others as leverage to accomplish ends at odds with its wording. Well-meaning agencies and professionals have used the report in their efforts to establish regulations requiring committee approval for the use of ECT in every case, a list of diagnoses for which ECT is prohibited, and the control of the use of ECT by statute. These efforts were justified by their proponents on the basis of sections of the report taken out of context and interpreted in a manner different from the report's expressed purpose. Other professionals, despite their regard for the caliber of the task force members with opinions different from their own, have been tempted to describe as malpractice those methods of treatment for schizophrenia about which they disagree.

EXPLANATIONS FOR DISAGREEMENT

It is astonishing to me that, in the absence of convincing data, large groups of fully trained professionals approach the practice of their calling at right angles to each other, displaying vehemence in support of their own positions that increases in proportion to the earnestness of their critics. It is this phenomenon—the exclusion of or inability to entertain a viewpoint different from one's own—that compels us to try to fathom it. Of course it would be unfair to conclude that all psychiatrists, in one way or another, stand at daggers drawn. For the most part they work in individual practices or in association with hospitals and agencies having an orientation similar to their own, and they reinforce their attitudes by discussing clinical issues almost solely with peers of similar persuasion. Although the gap may have narrowed among some of the other therapies directed at individuals, groups, and families, or involving methods dependent on deconditioning, psychodynamic insight, medication, and community programs, attitudes regarding ECT have remained singularly entrenched. Most psychiatrists either believe in the value of ECT and administer it, or they avoid it almost entirely. It is only in rare instances that they refer a patient to a colleague whose practice is different from their own for an evaluation for alternative treatment; this may be more frequent in institutions where a multidisciplinary approach is encouraged. How may we attempt to understand these staunch beliefs, which endure without any convincing long-term comparative studies of the effectiveness of ECT, psychotherapy, medication, milieu factors, or combinations of these methods in the treatment of conditions like schizophrenia or complicated depression?

Three categories of reasons seem likely to explain this special behavior associated with ECT. The first is the often quoted personal investment of time and effort (not to mention financial resources) to master and then have the opportunity to practice special skills. However, if we adhere too closely to this as the main factor motivating the behavior, we lose sight of the fact that many psychiatrists in training have had an opportunity early in their careers to choose between the psychodynamic and the more biologically oriented approaches and have responded more to the qualities of one than to the other, even before receiving much instruction.

This leads to the second category, which probably reflects the personality qualities of the trainees (hinted at above). Those sympathetic to reflection and introspection, who are psychologically minded and not primarily people of action, are probably attracted to the psychodynamic style of treating psychiatric illness. By training—but possibly also by choice—such individuals become reluctant to engage in physical contact with the patient. Those favoring the biological approach seem eager to apply the training acquired in medicine and surgery, which not only encourages but demands bodily contact with the patient. Nonmedical mental health workers include this style in the term "medical model." Because of their own interests, training, and experience the majority of them tend to favor individual or group psychotherapy or environmental programs.

The third category includes the reasons that flow from the reinforcement of successful clinical experience. Both those who use ECT and those who do not are thanked by grateful patients who appear to have improved. Some patients yearn for understanding or insight; others prefer more immediate relief. Whatever the criteria of improvement used by patients and their families, the reported success of a treatment reinforces the professional's belief in himself and in his style of practice.

SIMILARITY TO RELIGIOUS BIAS

In whichever way these reasons exist or combine, they seem capable of precipitating an effective mechanism for defense against uncertainty—namely, that of denial. The move to closure without all the clues and the commitment to one of two seemingly mutually exclusive choices are hallmarks of such a defense. The fervor with which the belief systems are subsequently upheld is strongly reminiscent of religious bias.

My purpose in this report is to encourage patience with, and a tolerance for, ambiguity and uncertainty. This is especially pertinent in the study of the behavioral sciences, where, at present, we are more dependent for our conclusions on accumulated experience and knowledge than on reason and logic. Postponing closure, with its denial of alternatives, may well lead to the discovery that treatment styles are not mutually exclusive, that psychotherapy and ECT may both appropriately be combined with other treatment methods, and that only by comparing the results of different methods in a well-planned prospective study will a logical preference be feasible.

How To Avoid Taking the Boards but Save Face

BY DANIEL Y. PATTERSON, M.D.

The author presents several options for other psychiatrists who wish to avoid taking board examinations and still save face. Although the author states that none of these worked for him, he wishes to present his suggestions to others in the field.

BOARD CERTIFICATION (and, unfortunately, recertification) will become increasingly important in the future. Position appointments and eligibility to practice (or to be paid for practice) may soon depend on board certification. Two years ago, after two and a half years in an administrative post with the federal government, I was appointed chief of psychiatry of a large prepaid multispecialty group practice. The chiefs of the other medical services, already board certified in their medical specialties, had made the assumption that I would "get the boards out of the way" in the coming year. Although board eligible, I had not seen a patient for what seemed a very long time. The other department heads talked about "getting your boards" as if it were as easy as getting your state medical license by reciprocity. What if I failed the boards? How embarrassing! I began to ask myself the question, "How could I avoid taking the boards but save face?"

My initial thoughts were temporizing measures—illness in the family, taking boards was too expensive, my new job was too time-consuming, etc. Although these reprieves could be used in parallel or sequentially, I knew they would run out in time. I began to search for a more permanent solution to my problem. After much deep thought (and conniving) I came up with a variety of options (I learned that word when I was a bureaucrat).

OPTION 1: PRESTIGIOUS RESIDENCY: "WHO CAN EXAMINE ME?"

Why not? I had trained at Johns Hopkins Hospital, where Adolph Meyer's ghost still stalks the halls. Hopkins-trained internists had taken this tack in years past. Why couldn't it work for me? But this approach seemed too "uppity."

OPTION 2: SCATHING ATTACK ON THE VALIDITY OF THE BOARD EXAM

If only I had been farsighted enough to coauthor the paper on the pseudo-regulation of American psychiatry written by two of my friends (1)! Even if I hadn't worked

Dr. Patterson is Chief of Psychiatry, Group Health Association, Inc., 2121 Pennsylvania Ave., N.W., Washington, D.C. 20237.

on the paper, they might have acknowledged my "help" if I had asked nicely. Having been coauthor or "honorably mentioned," I would have gone on record as to the inauthenticity of the present certification procedure and could have claimed that the present board would be "out to get me" were I to take the exam. My one major reservation about choosing this course was that the American Board of Psychiatry and Neurology might institute the changes suggested in the article; then where would I be? The proposed changes seemed unrealistic enough (e.g., "Other human service professionals and lay advocates should be added as members of the American Board of Psychiatry and Neurology ...." and "establishment of proficiency standards for psychiatric practice ...." [1, p. 661]). A few years ago I would have felt safe, but lately there have been changes in the American Psychiatric Association that no one would have predicted, haven't there? Who knows what might happen in the next few years? I discarded this option as being too risky.

OPTION 3: PSYCHOANALYTIC PRACTICE OR ADMINISTRATIVE PSYCHIATRY DODGE

Friends of mine who were in analytic training were able to dismiss the boards as "irrelevant." Why couldn't my interest and career choice (administration) allow me the same dodge? Unfortunately, I was up to my ears in clinical practice and would be for years to come. What was worse, the other chiefs of departments where I practiced were into a kind of clinical machismo that said "Not only are we good administrators, but we are the best [insert internist, pediatrician, obstetrician, etc.] in the department." I knew this option would never work for me. At this point I was getting desperate. I strained harder for a workable solution.

OPTION 4: PERMANENT INELIGIBILITY FOR BOARDS ON A TECHNICALITY

I rushed to examine the requirements for board eligibility. Could I find a technicality that would make me permanently ineligible for boards without additional training? No one would expect me to give up my present post to go back to get further training. Since I had already applied and been declared eligible for boards, it would be somewhat embarrassing to bring to the board's attention the technicality that made me ineligible, but I no longer had any pride. Even after careful review and rereview I could not come up with a solid case for ineligibility. I had some arguments but nothing "hard" enough to make the board reverse itself. Anyway, choosing this course of action was like shooting off one's big toe to avoid the draft. Who wants to walk around a professional cripple all his life?

OPTION 5: ECCENTRIC OR LIBERAL PROTEST

Since psychiatrists seem to have a societal license to be eccentric, could that not be adequate grounds for refusing to take boards? Alas, I was not the eccentric type. I have never had a beard or long hair. I even practice in a tie and business suit. Could my not taking the boards be a part of a politically activist or counterculture protest? Again, I'm just not a symbolic protester. I paid my income tax even during the Viet Nam War. Although I consider myself liberally inclined and work for issues I believe in, I've never demonstrated or gone on strike. I would even eat nonunion lettuce and grapes if it would be embarrassing not to.

NO MORE OPTIONS

Having exhausted my options, I resigned myself to my fate. Realizing, however, that other psychiatrists face this same dilemma, I felt it would be a contribution "to the literature" to document the options available to those who want to know how to avoid taking the boards and save face.

The *Curandero*'s Apprentice: A Therapeutic Integration of Folk and Medical Healing

BY JEROLD J. KREISMAN, M.D.

The author discusses alternative methods for dealing with folk illness in psychotherapy. Two case reports are presented that describe psychotic Mexican-American patients who were successfully treated with an approach that integrated curanderismo, *the Hispanic concept of healing, and traditional therapy. The author discusses ethical aspects of this integrated approach and suggests that cultural considerations can be successfully incorporated into a treatment plan of optimum benefit for the individual patient.*

MODERN PSYCHIATRY must extend treatment to people of many different backgrounds. However, such assistance often fails to acknowledge and work within an individual's cultural frame of reference. The Hispanic population is Denver's largest minority group, and, despite acculturation, the Hispanic culture is pervasive in many areas, particularly the concept of illness (1, 2). Unfortunately, there is little integration of these unique cultural considerations into a definitive treatment plan for Spanish-speaking patients.

This paper describes two cases involving Mexican-American schizophrenic patients in which conventional therapy was seriously stalled until treatment was adapted to the patients' culturally bound concept of their illness. The therapy was modified to conform appropriately to a model of *curanderismo*, the Hispanic concept of healing (2–4).

THE MEXICAN-AMERICAN FAMILY AND THE CURANDERO

As others have noted (1–4), the Mexican-American family is typically a tightly knit unit; distrust of agencies outside this unit prevails. Since illness may be perceived as a hereditary defect, the family strives to determine that a member's illness is due to external, extrafamilial factors, often seeking the services of a *curandero* (healer), who will support such an etiology. The *curandero* is a very religious and highly respected member of the community who retains many of the customs of Mexico, maintaining cultural bonds for even the acculturated Mexican-American.

Case Reports

Case 1. J.S., a 31-year-old Mexican-American woman, was brought to the hospital by the police because of disorganized, bizarre speech and behavior. She had been hospitalized twice previously with a diagnosis of paranoid schizophrenia. At the time of admission, the patient was confused, suspicious, resistive, and actively hallucinating.

On the ward, she was given trifluoperazine and she partially reintegrated over a two-week period. Although oriented and exhibiting more appropriate behavior, she remained withdrawn and secretive. She vaguely but inconsistently acknowledged auditory hallucinations and continued her reticence in psychotherapy, exhibiting no insight.

After several weeks of stalled therapy, the suggestion was introduced that she might be *embrujada* (bewitched). She responded with great affect and relief, confirming the suggestion and expressing surprise at the therapist's grasp of the problem. At that point, the therapist described a course of *curanderismo*, relating that he had worked with a *curandera* who had granted him use of her herbs in combination with a prescribed ritualistic regimen designed for victims of *embrujada*. The therapy included prayer, isolation, and personal deprivation, in combination with the prescribed herbs—actually doxepin hydrochloride (Sinequan).

She described immediate improvement when the course of *curanderismo* was added to the regimen and has functioned well since discharge. There has been a marked deemphasis of the etiological significance of the folk illness, although upon direct questioning she confirms that she is no longer troubled by "spirits." More important, immediately following discussion of her concept of her illness, the patient for the first time began openly revealing and discussing pertinent parts of her history and important intrapersonal conflicts.

A later difficulty involving the transfer of her case to an outpatient therapist was resolved by a joint meeting with the patient and the two therapists, during which the new therapist expressed understanding of the patient's concept of her illness.

Case 2. D.M., a 22-year-old unmarried Mexican-American woman, was admitted for the first time to the hospital with psychotic behavior one week after the birth of her first child. At the time of admission, she appeared grossly psychotic and suspicious, divulging little information. She was given haloperidol and improved within several days, although she retained a markedly flat affect.

She was discharged after two weeks in the hospital, but was readmitted one week later with the recurrence of symptoms. At the time of her readmission she also exhibited significant signs of depression. After antidepressants were added to the haloperidol regimen, she again partially recompensated, but the flat and inappropriate affect persisted. Her family clamored loudly for

At the time this work was done, Dr. Kreisman was a resident in training at Denver General Hospital, Denver, Colo. He is now a commissioned officer in the U.S. Public Health Service and a resident in training at St. Elizabeths Hospital, Dix Building, Washington, D.C. 20032.

The author wishes to express his appreciation to the staff of the psychiatric unit, Denver General Hospital, and to Stephen Dilts, M.D., for encouragement and suggestions in the preparation of this paper.

her release, simultaneously expressing dissatisfaction with the hospital's treatment and the conviction that the patient was well enough to return home. The patient continued to be very resistant and the therapy was stalled.

At this point, the patient told a Mexican-American staff member about the possibility that a hospitalized patient might actually be "hexed." At a subsequent interview, the therapist remarked that he had observed a similar case in which a patient had felt she was *embrujada*. The patient responded enthusiastically to this suggestion, acknowledging that her mother had been trying to find a *curandero* for her.

She eagerly responded to a proposal to utilize the *curandero*'s herbs in the hospital and rigorously prepared herself for the ordeal with prayer and isolation. She also devised specific criteria by which she could judge when she was no longer *embrujada*. Her improvement in the hospital continued but, although acknowledging she was regaining her health, she insisted that only after receiving the *curandero*'s magic would she be totally cured.

Prior to the initiation of the hospital *curanderismo*, the patient, while on a pass, was taken by her mother to a local *curandera* who administered "medicine." She returned to the hospital complaining of xerostomia, blurred vision, tremulousness, and the return of persecutory auditory hallucinations. She also exhibited nystagmus, mydriasis, and tachycardia. As her symptoms persisted over the next few days, the patient requested the hospital *curandero*'s herbs, which she felt could counteract the local healer's drug. Within one day after initiation of the regimen (doxepin hydrochloride), her symptoms disappeared and she had also fulfilled her own criteria that indicated she was free of *embrujada*.

Over the next several weeks the patient began to progress significantly in psychotherapy and a firm rapport was solidified with her as well as with her previously hostile family. However, she retained a markedly flat and often inappropriate affect, failing to regain her state of health before her encounter with the local *curandera*. A course of electroconvulsive treatment was eventually initiated, and the patient responded exceptionally well. She has regained her premorbid status, retaining her previous job and assuming mothering responsibility for her child.

COMMENT

Psychiatric treatment often displays little regard for an individual's cultural frame of reference. The two cases I have described represent an attempt to actively integrate modern mental health resources within a framework of a Hispanic concept of folk illness. Such an approach in this particular culture has not been extensively investigated, although the success of folk healers is well documented (3–6).

A recent article (7) did describe an attempt to treat 15 cases of *embrujada* within the appropriate cultural framework. The authors stated that 12 of their 15 patients were markedly improved when treatment included the suggestion that the medication was derived from the *curandero*'s herbs of northern Mexico. In these cases, however, the subject of *embrujada* was not openly discussed. Further, the 3 failures in this study were the 3 psychotic patients. Kiev (3) has also observed that *curanderismo* tends to be less successful in psychotic patients. However, in the two cases I have described, both schizophrenic patients responded well to a *curanderismo* regimen in conjunction with somatic treatment and psychotherapy. Such an approach may indeed be a useful—perhaps even necessary—supplement in the treatment of psychotic patients of Hispanic backgrounds.

TREATING FOLK ILLNESS

Recognizing the Problem

A major problem in dealing with folk illness is recognizing when this concept is a significant factor in the malady. It may not be necessary to explore this ground unless the patient's conflicting view of his illness interferes with therapy. However, as Casper and Philippus (7) emphasized, it is unusual for the Mexican-American patient to volunteer to the Anglo therapist the belief that he is *embrujada*, although he may well respond enthusiastically to such a suggestion from the psychiatric worker. Therefore, the therapist must be aware of subtle signs which indicate that a patient's concept of cultural illness is conflicting with a traditional therapeutic program.

As the case reports I have presented illustrate, patients in whom such a conflict exists may display mistrust and evasiveness, often as a reflection of their inability to translate culturally defined concepts of disease to a socioculturally distant therapist.

Another possible indication of the existence of a problem is the achievement of a plateau stage wherein the patient fails to progress following initial improvement on medication. Although better integrated, he may display significant discomfort in psychotherapy sessions. At the first sign of improvement, the patient may demand discharge, despite an awareness that he is not yet well. This demand may be the patient's expression of his conviction that he must seek a *curandero* for definitive treatment.

Probably the most significant indicator in the recognition of folk illness as a significant factor in a patient's psychopathology is the reaction of the family. They may demand the patient's release, expressing a desire to take the patient to their private doctor and criticizing the hospital care. This usually reflects the family's anxiety over the patient's illness and their conviction that he will not regain his health until the *curandero* intervenes.

Approaches to Treatment

If the therapist feels that folk illness is a significant factor in a patient's illness, he is faced with the dilemma of how best to confront this issue. Several alternatives are available and may be referred to as approaches that ignore, compete, cooperate, or integrate.

The first approach, the most obvious as well as the most frequently used, is to totally ignore the patient's concept of his disease, dealing only with a medically oriented model. The prevalence of this attitude stems primarily from ignorance of an individual patient's frame of reference. Although this approach may be acceptable in some cases, it is probable that few patients are best treated by completely ignoring their cultural biases.

The second approach is to acknowledge and discuss the patient's concept of his illness but to compete against it. The traditional medical view of disease is offered as the one true, rational construct; the patient's own culturally based understanding is denigrated. Although some patients may respond to an outsider's admonitions that the folk explanation of illness is nonrational, logical argument cannot pretend to negate an individual's lifetime training.

A third alternative is the cooperative approach, in which the therapist benignly accepts the patient's concept of his illness and avoids competition with this belief. Here, traditional psychiatric care and *curanderismo* maintain a kind of separate but equal status. The patient's realization that the Anglo doctor may truly appreciate the problem in its proper context may encourage him to open up further in therapy.

Unfortunately, however, this approach may require an impossible degree of rapprochement between folk and medical sciences. In legitimizing but not specifically using the folk interpretation of illness, the psychiatric worker implicitly accepts the role of the outside *curandero* in the therapy program. Except in the rare instance in which the therapist and the *curandero* can work cooperatively, introduction of the *curandero* will usually interfere with treatment.

In the approach that stresses integration, the therapist may not only accept the patient's cultural beliefs but may encourage their expression, actively seeking to integrate his therapeutic regimen within a framework consistent with the patient's understnding. The therapeusis is employed within the appropriate cultural bias, but unpredictable outside forces are not introduced. Folk and scientific treatments are equal but not separate in this approach; they are integrated under the total control of the therapist. Such a technique was utilized with success in the two cases I have cited.

Advantages of Introducing Curanderismo

Dealing directly with a patient's cultural view of his illness may complicate therapy by introducing many new variables. However, such confrontation can have a very positive effect on the treatment. The most obvious advantage is the increase in rapport and trust within a therapeutic alliance. The therapist demonstrates a true grasp of the patient's anguish within the patient's own frame of reference. In both of the cases I have described, a working therapeutic alliance was not established until the therapist clearly demonstrated this understanding. Interestingly, however, once this area was approached openly, the entire topic of folk illness ceased being an issue, as Casper and Philippus (7) have also noted.

Another important advantage of this technique is the enlistment of family involvement and support. In case 2, the previously hostile family attitude abruptly changed following the therapist's acceptance of the concept of *embrujada* and his successful use of *curanderismo*. Indeed, this confidence in the psychiatrist encouraged the family to contact him when the patient suffered the ill effects of the local *curandera*'s herbs. The family revealed that without this relationship, they would have declined to contact a resource within the medical system at that critical time. The enlistment of family support in a society in which this unit is a primary force is essential in insuring cooperation in both short- and long-term treatment plans. This fact is especially well understood by the *curandero*, whose initial energies in treatment are directed toward achieving family support and cooperation (3).

Ethical Issues

An important issue raised by this integrated approach to psychiatric treatment in a culturally distinct minority population is that of morality. What are the ethics of a non-Hispanic therapist invoking Hispanic ritual in his treatment plan? By unconditionally accepting the patient's precepts, is he fostering a delusional system that he should be attempting to alter? One might argue that the folk concept of illness is not a true pathological delusion, but rather a culturally developed, culturally acceptable belief that is as resistant to challenge as is that of a devoutly religious individual who claims to hear the voice of God.

Perhaps a more difficult issue involves the therapist's role as *curandero*. In one view, he is working within a patient's cultural frame of reference, exploiting a position of authority in achieving a suggested placebo effect. But does he cross the nebulous boundary between firm suggestion and outright fraud? It might be argued that a therapist using this technique differs little from a general practitioner offering subtherapeutic doses of a minor tranquilizer to his chronically somatizing patient together with strong incantations that the medication will cure him. In this country's cultural setting, in which pills can magically cure any ailment, such a physician is merely fulfilling a culturally defined role as healer. Nevertheless, it is certainly presumptuous for an Anglo therapist to interject himself into the Mexican-American cultural system, a system he cannot fully appreciate. And yet, perhaps this does not entirely preclude his working in such an area, just as a male obstetrician can still empathize with a woman's labor and offer valuable assistance to her at that time.

LETTERS TO THE EDITOR

On the Evolution of Neurotic Maladaptations

SIR: I would like to take issue with the conclusions A.D. Jonas, M.D., and D.F. Jonas expressed in their article "The Evolutionary Mechanisms of Neurotic Behavior" (June 1974 issue). Having referred to the relatively helpless state of the human infant, they see the "slowing of developmental processes" in man as contributing to man's intellectual growth and opening the way to the "emergence of phylogenetically early responses." They conclude that "many of the maladaptive behavior patterns labeled as neurotic result from man's retention of archaic responses." Impressed by the maladaptive components of neurotic behavior, they do not see them as fulfilling any biological function. In order to account for the presence of neurotic maladaptations they label them as "archaic responses."

My first criticism is that the authors have overlooked the work of Price (1), who used ethology to define one biological function for human neurotic reactions. He described such reactions as having evolved as the "yielding component of ritual agonistic behaviour," i.e., avoiding violent confrontation in competitive situations aided the survival of the individuals involved and therefore of the race.

My criticism of the Jonases' conclusions stems mainly from my belief that an important biological function for human neurosis can be defined, i.e., promoting man's intellectual growth. Maladaptive behaviors labeled as neurotic reflect and in turn contribute to the human organism's maladaptation to his environment. Neurotic maladaptation is therefore a vicious circle: the impact of small genetic differences in viability between competing organisms may be magnified and the initial difference in viability between them may be greatly increased.

For example, an individual who has a slight genetic disadvantage in relation to a competing person is likely to be the loser more often and thus more prone to develop feelings of inadequacy and frustration and neurotic maladaptive behavior patterns. If these humans were competing in a primitive environment, the increased neurotic behavior of the less successful competitor might significantly impair that individual's viability.

Neurotic maladaptation could therefore be viewed as an evolutionary mechanism that greatly accelerated the evolution of the human species during the pretechnological age. Although it may have had a negative impact at the level of the individual, it would have had a positive impact on the evolution of the human species by accelerating the process of natural selection. We do not directly inherit neurotic traits, but all of us have the potential to develop neurotic symptoms under adverse circumstances (2).

In view of the fact that chance mutations that have a favorable influence on man's intelligence are likely to have minuscule effects, the magnification of impact (resulting from increased neurotic maladaptation of lesser endowed competitors) has probably contributed significantly to man's intellectual development.

Price's hypothesis and my own are not necessarily mutually exclusive. It could be argued that neurotic individuals who have experienced frequent failures might be more submissive or yielding.

In summary, my argument is that human neurotic reactions may have had a much more comprehensive biological function in the pretechnological era of human evolution than has been suggested.

LEON SLOMAN, M.D.
Toronto, Ont., Canada

The Jonases Reply

SIR: When one deals with a complex subject consisting of many subsystems, one has to recognize it as such. A failure to do so results in a view of the complex subject as admitting only one truth.

Dr. Sloman deals with an end result or effect of an emerging neurotic response as though it were a totality. The subject of our paper was a subsystem, i.e., the mechanisms that provide a variety of channels, into one or some of which an environmental stimulus enters, is elaborated, and emerges as a psychological and/or somatic response.

Dr. Sloman proposes that neurotic responses are adaptive in that they promote overcompensation in some individuals. We have no quarrel with this point of view. In fact, we have written extensively along these lines (1). However, when compensatory or displacement mechanisms lead to physical disability, shortening of life, sudden death (in cases of cardiac involvement), or behavioral malfunctions promoting serious social problems, we would seriously question any phylogenetically adaptive value.

We certainly agree with Dr. Sloman about the value of Price's work, with which we are familiar. Indeed, Dr. Price is a good friend and we have had many discussions with him on this topic. However, like Dr. Sloman, Dr. Price deals with an outcome and not with the mechanism that gives it form.

We believe that an understanding of those evolutionary mechanisms which promote psychological consequences gives a sounder theoretical basis for psychodynamic formulations, places etiological factors into a coherent scheme, and ultimately must result in more effective therapeutic measures.

On the *Journal* and the Moon

SIR: The appearance of "The Questionable Relationship Between Homicides and the Lunar Cycle" by Alex D. Pokorny, M.D., and Joseph Jachimczyk, M.D. (July 1974 issue) does a great disservice to this journal. Perhaps because of the scarcity of quantifiable data in the behavioral sciences, we psychiatrists are too attracted to reports that include graphs, charts, and statistics, especially when embellished with chi-square values and statements of statistical significance or the lack thereof.

The issue of proving or disproving that homicide or lunacy has anything to do with the moon is dignified greatly by the appearance of this study in the official publication of the American Psychiatric Association. Counting this article, *The American Journal of Psychiatry* can now claim to have published a total of five papers and one letter to the editor addressed to this ludicrous issue (1–5). Furthermore, the appearance of this article suggests to the profession that this is a reasonable area of research interest. Apparently some people have taken the old Lon Chaney, Jr., films seriously.

NORMAN B. LEVY, M.D.
Brooklyn, N.Y.

Dr. Pokorny Replies

SIR: I cannot speak for the general editorial policy of the *Journal* or for the content or emphasis of Dr. Levy's first four references. I would state, however, that there is a strong interest in the topic of our paper; many laymen and professionals seem fascinated by it. Furthermore, if there is a popular belief that moon phases influence behavior, such relationships may occur, even though they are mediated by psychological rather than physical influences.

The reports in which I have been involved have been consistently negative concerning the role of the moon in mental disorders. I believe Dr. Levy and I are on the same side; I too question the relationship between moon phases and such gross human events as homicide or suicide. The work of our group has consisted of a series of unsuccessful attempts to replicate a number of positive reports. In my opinion it is better to do this with data—including graphs, charts, and statistics—than to simply dismiss the question as "this ludicrous issue."

Houston, Tex.

Person-to-Person Therapy

SIR: Every once in a while I read something in the pages of this journal so incredible that I have to respond. A case in point is the letter from Myron F. Weiner, M.D. ("Self-Disclosure by the Therapist," August 1974 issue) concerning Leston L. Havens' article "The Existential Use of the Self" (January 1974 issue).

If I understand him correctly, Dr. Weiner says that therapists must be careful with the technique of using the self, that there are definite indications and contraindications. He says:

> The chief indication for the therapist to reveal his feelings is when the treatment need of the patient requires that the therapist relate as a feeling person. This occurs at certain stages of the treatment of many types of patients but *only when there is an adequate bond between patient and therapist* [italics mine] . . . . The average patient who is recovering from an emotional upset has little need to experience his therapist as a person if he has been able to make use of suggestions, environmental manipulation, or medication.

In my opinion, Dr. Weiner's statement is backwards. I think such techniques as silence, objectivity, and withholding are fine if an adequate bond has already been established, and that the therapist relating to his patient as a person is the only way to establish such a bond.

I would feel foolish even saying this, since it seems so obvious, but for the fact that the opposite is taught as dogma in so many mental health training programs. My experience has been that the only thing that really helps a person experiencing emotional crisis is another person letting him know that he has been there and understands. The next best thing is someone who, although he has not been there, is willing to be honest about where he is, e.g., wanting to help but not knowing how.

I also disagree with the idea that only people experiencing emotional crisis want to register another person as real. If I have a new idea, I want to know how it strikes someone else. I do not want to share the idea with someone who will simply look objective and mask unspoken feelings.

Why do psychiatrists think it is wrong to act like human beings? If we really know more about mental health than most people, we do not have to worry; it will become obvious to our patients. Is Dr. Weiner's experience so different from mine that he really prefers suggestions, environmental manipulation, and medication to the honest clout of a real person?

Finally, I found it very disturbing that Dr. Havens, whose article I really liked, says in his response to Dr. Weiner that he was not advocating the use of the technique. Where is a young psychiatrist trying to be a human being to look for guidance?

PETER A. ROEMER, M.D.
Silver Spring, Md.

Dr. Weiner Replies

SIR: Dr. Roemer understands me correctly. What the ordinary psychiatric patient needs is a neutral professional helper, not an exposure to the feelings of his doctor.

The doctor must have sufficient acquaintance with his patient and with himself to calculate (that's right, calculate) the probable impact of his real self on the patient. The "honest clout of a real person" may be exactly that: a good, hard clout that relieves the therapist and leaves the patient to cope with the therapist's feelings as well as his own.

A young psychiatrist trying to be a human being should first look outside his practice, to his family and friends. If he is un-

able to be a person in this area of life, he should consider therapy for himself. Becoming a patient in a therapy group is an excellent means by which a therapist can obtain interpersonal feedback.

Psychiatrists do not think it is wrong to act like human beings. Most of us do. But we do not lead with our humanness; we lead with our experience. Being human with patients, like displaying one's sense of humor (1), comes later, after both therapist and patient are certain that the patient is willing and able to get to know his therapist. Patients are not usually so fragile that they will crumble under an awareness of the therapist as a person, but the therapist can help set up unresolvable resistances by early disclosures of his prejudices, weaknesses, or needs (2). This kind of disclosure simply distracts from the real business of therapy—the patient's getting to know himself.

Being neutral in the early stages of therapy and even when the patient is demanding "realness" from the therapist is not always a cop-out. It is the best assurance the therapist can have that he is not exploiting the patient for his own emotional needs. The therapist's neutrality (not impassiveness) can help to get across two important points: that the patient needs to turn to someone other than the therapist for satisfaction of the bulk of his emotional needs and that the therapist is entitled to his own privacy.

Neutrality is the best way for the therapist to avoid exploitation of the patient for his own emotional needs and gives the patient less encouragement to demand that the therapist meet, rather than help him understand, his own emotional needs.

To sum up, the therapist owes a patient his professional expertise, not himself (3).

Dallas, Tex.

Dr. Havens Replies

SIR: The fact that there are forces in clinical situations that require careful handling, especially transference and countertransference, coupled with the fact that "acting like a human being" does not necessarily mean acting like a mature or even a sensible one, makes technical advice necessary. In other words, a general formula such as "act like a human being" is as bad as its opposite, "never act like a human being." We have to have technical guidelines, even though I do not like the word "technique" either. Perhaps it would be better to say that we all occasionally need examination and adjustment of our perspectives.

I honestly believe that, beyond certain spontaneous intuitions and feelings, we do not know a great deal about when to act in a less than strictly professional manner in clinical situations. In my article I worked toward a description of the method or perspective of existential psychiatry because only by defining, applying, and studying it can we refine our knowledge of when to use it. That was the path psychoanalysis followed in the development of its method, and it seems appropriate here, too.

Boston, Mass.

EEG in Schizophrenia

SIR: I was most gratified to read the article by T.M. Itil, M.D., W. Hsu, M.S., B. Saletu, M.D., and S. Mednick, M.D., showing that the EEG may be used to detect high risk for schizophrenia in children ("Computer EEG and Auditory Evoked Potential Investigations in Children at High Risk for Schizophrenia," August 1974 issue).

In 1936, while I was working with Lord Adrian in England, a Russian by the name of Nicholi Propper and I recorded some EEGs on patients at the Cambridgeshire Mental Hospital. We transported on our bicycles the crude EEG machine we had built from the Cambridge University laboratory to the hospital where we recorded the brain waves.

It was my impression at the time that the schizophrenic patients in general had a low level of alpha activity (1). It is rewarding to have this confirmed by the sophisticated research of Dr. Itil and his colleagues.

I also postulated that low alpha activity in schizophrenia indicated poor synchronization of the visual cortical cells (2). It is interesting that other evidence of poor synchronization, such as in eye movements, is now being found in schizophrenia. Perhaps the basic physiopathology of schizophrenia is a lack of coordination of brain functions all the way from the cortical cells to the processes of feeling and thinking (3).

Seattle, Wash.

Capgras Syndrome in Male Siblings

SIR: In his article "The Capgras Syndrome and Its Psychopathology" (August 1974 issue), B. Frank Vogel, M.D., reported that most of the cases of this syndrome in the literature involved women and that the five patients he treated were women.

I have reported (1, 2) on the occurrence of this symptom complex in a 12-year-old boy whom I was able to follow for five years. His preoccupation with doubles, fakes, and aliens continued intermittently throughout the nine months he was in treatment. He responded to oral chlorpromazine (Thorazine) and to repeated interpretation of his symptoms in terms of the changing and conflicting feelings he had for his parents, the accused doubles.

His symptoms were seen in the context of the disordered communication within his family; his parents were also treated. When some interpersonal family tensions had been relieved, the symptoms disappeared in the patient, but they reappeared in his brother.

The younger brother also believed that his parents were benevolent doubles. Because intense rivalry had existed between the two boys, one might expect that this was a competitive identification. However, the younger brother's affect demonstrated that his belief had a deep emotional impact for him. In contrast to Dr. Vogel's patients, these boys were terrified in the presence of the threatening doubles. The younger brother had the illness for about one year, finally responding to treatment similar to what I had used with his brother.

The opportunity to study two instances of Capgras syndrome in the same family caused me to reflect on the role of parental influence in the syndrome. There was a strong history of schizophrenia on both sides of this family, but no other reported instance of belief in doubles. The mother was prone to describe people she knew as "two-faced."

Like Dr. Vogel, I believe that this symptom complex is much more common than one would assume from the number of descriptions in the literature. Children frequently split their parents into good and bad. Melanie Klein described the function of ambivalence states in the following way:

> Ambivalence carried out in a splitting of the imagoes enables the child to gain more trust and belief in its real objects and thus in its internalized ones. At the same time, the paranoid anxieties are directed to the "bad objects." (3, p. 308)

I suspect that this kind of psychological maneuver occurs in many if not all individuals as they grow up through childhood. It is unclear what causes it to persist or to reemerge under stress in particular persons.

A Transfusion for the Medical Model

SIR: I feel that "From Rationalization to Reason" by Seymour S. Kety, M.D. (September 1974 issue) should also appear in the *Journal of the American Medical Association.*

As I have watched those who are opposed to the medical model assault the medical-psychiatric approach to mental illness, I have wondered where the ethics committee of APA has been. To employ clever semantics to attack one's own profession seems to me untenable. Those of us who have been struggling to upgrade mental hospitals seem to have been deserted by our colleagues.

Dr. Kety's perspective is like a transfusion for mental hospitals, which are anemic in regard to morale, staffing ratios, and training programs. Identity crisis, indeed.

EUGENE J. FAUX, M.D.
Provo, Utah

Schizophrenia and Season of Birth

SIR: The article by Robert A. Woodruff, Jr., M.D., and associates (August 1974 issue) entitled "Psychiatric Illness and Season of Birth" is remarkable in two ways. First, it is remarkable that the authors would publish a study using only 22 schizophrenic patients as subjects. Their purpose was to determine the distribution of schizophrenic births among the months of the year (or signs of the zodiac, as they prefer), and it is impossible to conclude anything when only 22 subjects are distributed among 12 categories. The studies that have shown an excess of schizophrenic births in the winter months have used a total of more than 96,000 schizophrenic patients (1).

Second, the study is remarkable in having used signs of the zodiac rather than months of the year. The authors claim that they did this to make "esoteric and arcane speculation possible." Although this may be amusing, it does not do much to advance research on schizophrenia. There are several good hypotheses to explain why schizophrenics are born more frequently during winter months, including seasonal protein intake (2), a possible association with hemorrhagic disease of the newborn (1), and a possible association with virus infections (3).

The seasonal distribution of schizophrenic births has been clearly established. Our problem now is to develop reasonable theories of etiology that will encompass this and other facts known about the disease. Consigning the seasonal distribution to the realm of astrology with tongue in cheek will not make it go away.

More on Blame in Family Therapy

SIR: "Mistreatment of Patients' Families by Psychiatrists," by William S. Appleton, M.D. (June 1974 issue) is a long-awaited reevaluation of the family therapy movement and its place in current psychiatric teaching and treatment methods.

It is ironic that family therapists who have attacked the medical model have become entrapped in the same grandiose "I have an explanation for everything" attitude of the tough-minded organicists. The "blaming game" started with labeling mothers as "schizophrenogenic." (Arieti stated that 25 percent of the mothers of schizophrenic persons fit in this category [1], but recently he seems to have moved toward the interaction model, in which mother and child both contribute to the development of the psychopathology.) Next, the blame not only for the perpetuation but for the genesis of that disorder was shifted to the family.

It seems to me that theorizing based on sparse facts or a distorted cognition and perception of the human condition that is schizophrenia has compounded the hardship of patients and their families.

BOOK REVIEWS

The Psychology of Politics, *by William F. Stone. New York, N.Y., Free Press (Macmillan Publishing Co.), 1974, 278 pp., no price listed (paper).*

Based on personal experience in the field of politics, observations of political life in the United States, his professional background in psychology, and his wide reading in the field, the author attempts to present an integration of selected contributions from social and personality psychology relevant to an understanding of political behavior. He tries to make this book understandable to undergraduates. In view of the chaotic political scene of today and the apparent misapplication of political power, any attempt to help us understand man's motivation for public life and the factors that determine people's choices should be applauded. Stone's attempt is admirable in this respect; it is also largely successful.

In part 1, Introduction to the Study of Political Behavior, the author ranges from an analysis of factors that led to the growth and eventual deterioration of the Oneida community, one of the early communes, to a whirlwind tour of political psychology through the ages. He touches upon the ideas of Plato, Hobbes, Machiavelli, and, of course, Freud, Marx, Lasswell, and Lane. He also notes a modern survey research on the habits of American voters. All these areas are dealt with rather superficially (as the sophisticated psychiatric reader will realize instantly when he peruses the section titled Psychoanalysis and Society), but this seems consistent with the author's goal of educating the bright young mind.

Part 2 focuses on the individual and the way he learns political attitudes. Here we are introduced to Lewin's field theory, factors influencing character development, and the ways in which the individual eventually learns politically colored social reactions.

In part 3, Personality and Motivational Factors, the author discusses self-esteem, power, competence, the Machiavellian personality type, the authoritarian and democratic personality disposition, and the liberal-conservative dimension. The reader will gain insight into the rationale for selecting these particular personality variables for dissection, the technology of their measurement, and their possible use in predicting how specific individuals will behave in the political arena.

Part 4 takes us into the psychology of participation, leadership, ambition, changing political attitudes, and political choice. In the author's discussion of barriers to political participation, we learn that Americans suffer from severe voter apathy and that even in the most heated campaigns participation is disappointingly low here in comparison with other countries. In light of this fact, the author discusses at some length patterns of leadership, the traits of leaders that attract or repel the public, and the elements that made up the charisma of such personalities as Lenin, Gandhi, Franklin D. Roosevelt, and John F. Kennedy. The ways of approaching measurement of these subtle factors will intrigue the research-minded reader.

The author examines the concepts of image and attitude, particularly in relation to the acknowledged difficulty in changing political ideology and voting preferences. If we are to foster public enlightenment and concern for the quality and efficiency of government, these components must receive greater stress in the future.

The volume bears upon great and pervasive public issues. It asks: Can the world powers live in peace, or is war and nuclear annihilation inevitable? How long can the depletion of natural resources and the pollution of the environment continue? Can citizens have faith in their government? How can we induce men and women of great ability and integrity to pursue high office? How does one foster informed, concerned citizen participation so that excellent candidates are recognized and elected?

The theme of the individual in the community is seen as applying to four distinguishable groups: the masses, the elite, the national leaders, and dissident minorities. These groups and their many subgroups are striving for self-interest within a complex society directed by a political system full of foibles, tangles, and tensions. The search for a truly participatory form of democratic society always goes on; although our forefathers left us with a workable and imaginative instrument for self-government, its application to our changing world requires considerable modification. Hopeful developments that appear to increase political awareness of the American electorate are summarized in Stone's quotation from McCloskey (1964):

> "The extraordinary spread of education, rapid social mobility, urbanization, the proliferation of mass media that disseminate public information, the expansion of the middle class, the decline in the size and number of isolated rural groups, the reduction in the proportion of people with submarginal living standards, the incorporation of foreign and minority groups into the culture and their increasing entrance into the professions . . . ." (p. 264)

All of the problems taken up in this book are important. The knowledge available in the field of psychology of politics is meager. The treatment of this knowledge base is necessarily superficial in a volume encompassing so much, but the material is set forth with lucidity and accuracy and the author's style ought to engage the interests of the audience he seeks to enlighten, namely, the intelligent layman. The intelligentsia, on the other hand, may want to look further and deeper once their appetite is whetted by this overview. An excellent reference list of approximately 270 citations will be of assistance in that quest.

MILTON GREENBLATT, M.D.
Sepulveda, Calif.

Psychiatry and Law, *by Ralph Slovenko, LL.B., Ph.D. Boston, Mass., Little, Brown and Co., 1973, 686 pp., $28.50.*

During the past decade psychiatrists in every sector of our conglomerate discipline have confronted the cutting edge of the law. It is an abrasive edge set in the adversarial vise of the legal process. Most psychiatrists, myself among them, believe that the new onslaught of law has cut away at the psychiatric enterprise without adequate consideration or respect for our difficult mission—the provision of mental health care. In the name of

the Constitution and civil rights, serious impediments to the provision of mental health care have been erected, and the mentally ill, particularly the chronically mentally ill, have been abandoned to their rights.

Many state legislatures have followed the lead of the courts and pushed through sweeping reforms of their mental health laws without providing the funds or the alternative facilities that such changes mandate if treatment is to take place.

Even the so-called right-to-treatment suits have thus far resulted in the reduction of institution census rather than the improvement of quality of care. If psychiatry is to resist this assault, it must do more than grumble and cavil; it must inform itself, understand the relevant legal issues, and then provide direction to the necessary progress of law.

Ralph Slovenko's book on psychiatry and law is a helpful source of the necessary information. Its tone is far more sympathetic to the mission of psychiatry than any of the other texts and law review articles that have appeared recently, e.g., Kittrie's book (1). Dr. Slovenko, a law professor trained in clinical psychiatry, received the Manfred S. Guttmacher Award of the American Psychiatric Association at the 1974 annual meeting for this work.

The book reads easier and better than most texts on law and has a great deal to offer the average psychiatrist. It treats all of the critical areas, e.g., civil commitment, right to treatment, right to refuse treatment, confidentiality and privileged communication, divorce, child custody, testamentary capacity, and psychiatric malpractice. It presents briefly all of the relevant legal doctrines and has a well-chosen set of case illustrations with actual trial testimony, which puts clinical flesh on the legal bones. There is an excellent discussion of how the court deals with evidence, particularly with psychiatric testimony. The adversary structure of law is discussed as it affects psychiatric testimony, and the pros and cons are presented.

The virtue of the book is that it takes the naïve psychiatric reader on a guided tour of a complex field. It is therefore a useful introduction by a man who speaks our language and, by his example, encourages us to speak his. It is a Baedeker, however: it does not present serious original ideas and is not a definitive resource. In fact, judged as a major work, it leaves much to be desired. It is marred by disconcerting, if trivial, errors. It borrows passages from other authors without acknowledgment, and crucial areas of current concern such as sexual psychopath legislation, preventive detention, and the treatment of juveniles are given only cursory treatment.

Nonetheless, for the psychiatrist who wants to be shown through the Louvre on his or her two days in Paris, Slovenko is an admirable if expensive guide. One hopes that the tour will lead many to more prolonged and profound study.

ALAN A. STONE, M.D.
Cambridge, Mass.

The World of the Urban Working Class, *by Marc Fried. Cambridge, Mass., Harvard University Press, 1973, 404 pp., $15.00.*

This is a valuable reference for students of the relationship between social context and behavior. It concerns the world views and habitual action patterns of working people in Boston's West End, which have much in common with those of people of comparable socioeconomic status in stable industrial societies the world over.

The author's discussion of his data is enriched by a comparative social and historical perspective that enables him to deal comprehensively with such variables as ethnicity, migration, occupation, residence, community structure, and family roles. The impact of reality and of situational factors on values and aspirations as well as on styles of thinking, feeling, and acting inevitably receives much attention. Even these people, who are not of the lowest social class, must come to terms with their social powerlessness, the abrasive quality of daily life, and repeated minor crises and major disasters.

It is in the area of social relations that the findings are of greatest interest to the clinician. Fried identified the "overall imbeddedness in close-knit network relationships . . . the expansion of a kinship orientation to a wider realm of local friends and neighbors" as the feature that "uniquely typifies community life in the working class" (p. 226). This pattern of relating, with its complex ramifications, is ultimately understood as the product of a particular system of social stratification; the most powerful determinant of an individual's role functioning in many different areas is the position he holds in the social class structure.

The data are subject to psychological as well as sociological interpretation throughout the book. Variations in social class realities, for example, determine differences in the consequences of attitudes and personalities as they influence the likelihood of fulfillment or frustration in the effort to realize personal potentials.

The chapter on personality may be the least satisfying to the psychiatric reader. Despite his use of such familiar concepts as anxiety, self-esteem, and ego mastery, Fried makes no reference to the large body of social psychiatric literature. He also includes "extrapolations from pathological models" among the reasons why "personality characteristics of people in different social classes are generally ill understood" (p. 200). But this is quibbling. This organized presentation of a large and unique body of data is a major contribution. These data have great theoretical significance; their full exposition is being continued in further work in progress.

The presentation is enhanced by a final section on the methodology of conducting research with complex psychosocial variables over time in a large population.

EUGENE B. BRODY, M.D.
Baltimore, Md.

Psychoanalysis and Feminism, *by Juliet Mitchell. New York, N.Y., Pantheon Books (Random House), 1974, 435 pp., $8.95.*

This book attempts to demonstrate the relevance of psychoanalysis to the struggle of women in our contemporary patriarchal society. Unlike feminists who denounce Freud's views on women, Juliet Mitchell believes Freud made an important contribution to the understanding of women's role in our society. She asserts that many feminists do not appreciate Freud's contribution because they construe his observation that many women believe themselves to be inferior, passive, and submissive as a statement of his belief that women are inevitably doomed to an inferior role in society.

In order to clarify her argument against the currently fashionable feminist attacks on Freud, Mitchell reviews many of his basic concepts. Although it indicates considerable familiarity

with and understanding of Freud's writings, her presentation of the psychoanalytic view of femininity is limited by her uncritical acceptance of some of Freud's tenets, her incomplete discussion of others, and her inadequate consideration of those psychoanalysts who followed Freud but emended and extended his observations.

Since Mitchell believes the major issue in the oppression of women is the existence of a patriarchal society, she focuses on Freud's contribution to the understanding of patriarchy, especially in his development of the central role of the father in his formulation of the castration and Oedipus complexes. In her review of Freud, Mitchell portrays the father as the symbol of authority who threatens the boy with castration unless he relinquishes his mother. To avoid this the boy detaches himself from his mother, identifies with his father, and internalizes the father's superego. The already castrated girl accepts her inferior status and submits to the father rather than identifying with him. Thus culture is transmitted by men via the superego, patriarchy is established, and women passively submit to men.

While she recognizes that social factors affect personality development, Mitchell is critical of those who attack Freud for not being sufficiently cognizant of social reality. She believes that this position overlooks the essence of the contribution of psychoanalysis. In her analysis of the work of Reich, Laing, De Beauvoir, and others, she demonstrates their misunderstanding of the concept of the unconscious, their confusion of social and psychic reality, and their tendency to offer utopian and reductionistic solutions.

Unfortunately, Mitchell's solution is as simplistic as some of those she criticizes. She believes patriarchy must be overthrown to end the oppression of women. The arguments on which she bases this conclusion as well as her suggestions for its implementation are difficult to follow. She has been impressed in her reading of Freud by the unconscious determinants of patriarchy. However, she believes that Freud did not go far enough and she turns to Lévi-Strauss to complete her argument. She accepts Lévi-Strauss' controversial thesis that in all societies women are used by men as a medium of exchange to maintain kinship relationships and guarantee exogamy. She views the maintenance of exogamy as a social issue.

Her argument alternates between the psychological and the sociological and her position is not clear. On the one hand, she speaks of the "eternal unconscious"; on the other, she suggests that a different organization of society will change unconscious representations. She advocates major social and economic revolutions that will establish a society in which economic exploitation will disappear and patriarchy will have no place. If patriarchy has no place in society, she argues, its unconscious representations will disappear and there will be no exploitation of women.

This book only partially fulfills its promise to demonstrate the relevance of psychoanalysis to feminism. The author's narrow focus on patriarchy omits many psychoanalytic contributions to the understanding of women, particularly the importance of preoedipal factors in determining gender role. Her wishful solutions neglect many important issues, including one of particular importance to psychoanalysis; i.e., she does not come to grips with the reasons for the dominant role of men in society. Is it the unconscious representation of maleness as a fixed symbol of power or is it attributes such as greater physical strength associated with maleness that determines the assignment of the dominant role in society to men?

We do not yet know the relative strength of unconscious factors and social forces in determining the respective roles and relationships of men and women. Although Juliet Mitchell's book does not adequately deal with these and other matters, it is a useful addition to the literature on feminism because it points out some of the contributions of psychoanalysis to the understanding of women's role in society and raises questions for further exploration.

REBECCA Z. SOLOMON, M.D.
Hartford, Conn.

Beyond the Best Interests of the Child, *by Joseph Goldstein, Anna Freud, and Albert J. Solnit. New York, N.Y., Free Press (Macmillan Publishing Co.), 1973, 161 pp., $7.95.*

This concise, remarkable monograph stands alone as the definitive exposition of one of the most difficult areas in the interface between psychiatry and law, i.e., what the rights of children are under the law, specifically in placement procedures.

The history of children and the law in America is a sordid tale of neglect and abuse. Colonial America regarded children as important tools of colonization. In terms of dependent children, the law required that they become indentured slaves ("binding out"). The custom grew out of English practice and law, the purpose of which was to reduce vagrancy and provide a form of social control over dependent children. Children reaching "suitable age" were bound out to serve farmers, tradesmen, sea captains, and others. Freeborn boys and girls were placed in involuntary servitude for no other reason than that they were poor. The driving principle behind the disposition of children was the absolute authority of the natural parents to do whatever they pleased with their children.

The reader of this monograph finds, tragically, that the rights of children in placement situations are never considered under current legal practices. The authors have used a simple but very efficient format. The basic parts of the book deal with the problem, suggested guidelines for child placement, including a provision for a model child placement statute, and a final review of their premises.

The authors are careful to define both familiar and new terms for the reader, for example, " 'Child placement' ... encompasses all legislative, judicial, and executive decisions generally or specifically concerned with establishing, administering, or rearranging parent-child relationships" (p. 5). The "wanted child" is one who receives affection and support on a regular basis from at least one adult who values him or her. I feel that this is the most critical definition in the book because it clearly indicates that any caring adult may establish the intimate relationship the law and society prefer to limit to natural parents.

This is the message that runs throughout the book. The only relationship that should be protected by law is one between a child and any adult who brings the intimate, loving relationship to the child that transforms him or her into a wanted child. Yet time and time again we witness placement based on concepts of the rights of biological parents and institutional rights. In vain do we and the authors look for placement based on the rights of the child.

The input of psychoanalytic concepts strengthens the stern legal jargon used throughout the book. At times it reads like a legal handbook, but this is understandable in light of the fact that the authors propose a model child placement statute. They are to be congratulated for moving beyond mere theory and pious pronouncements. In the best legal sense, legal revisions are offered, decisions quoted, and rationale presented.

The authors' reference material is excellent, although I was surprised to find no reference to the book of Sanford N. Katz published in 1971 (1). Katz wrote in a similar style and on a

similar subject. His work relates to studies accomplished at the Yale Law School while he was working under two of the authors of this book.

This is indeed a classic work. One only hopes that its message will bring about significant reform of the placement laws as applied to children.

A "Bill of Rights" for Children, *by Henry H. Foster, Jr. Springfield, Ill., Charles C Thomas, 1974, 83 pp., $7.50; $4.95 (paper).*

While introducing a course in forensic child psychiatry to a group of child Fellows, I was dismayed to find that there was no collected body of literature in this area. As a substitute for a text, I used a variety of articles, including a paper I felt would subsequently become a classic entitled "A Bill of Rights for Children" (1). When asked to review this book, I was delighted to discover that Prof. Foster's original article had been expanded to monograph form.

In the preface, Foster describes the origins of this monograph. In 1967 the regular course in family law at New York University was separated into two interrelated courses. The second of these courses, taught by Foster, was titled Children and the Law. Foster faced essentially the same problem I did because of the lack of compiled materials available on the subject. He gathered his material from diverse sources. In surveying the relevant literature in the process of preparing for his course, it became clear to him that the status of children was oppressive and that the usual assumptions were open to question. He further noted that children were rebelling because, like women and slaves, a legal structure theoretically designed to protect their rights was in fact serving to oppress and disenfranchise them. He concluded that children needed a new bill of rights.

The body of Foster's book is an explanation of what he proposes as a bill of rights for children. He makes it clear that although his focus is on the legal rights of children and not their educational, counseling, and larger philosophical problems, he does not believe that these should be ignored. Since he is a lawyer, his perspective focuses on the legal status of youngsters and the administration of justice in those areas which are within his area of expertise.

The format of the book introduces the subject of a children's bill of rights and then devotes a chapter to each of eight carefully defined rights. Foster quotes relevant case law to demonstrate where the law supports or neglects to support each of these rights. As one reads the book, it becomes apparent that these fundamental rights of children are not universally backed by law. Unfortunately, when there is existing law to provide muscle for the enforcement of a right, the administration of the law is often clumsy, unwieldy, cumbersome, and ineffective.

No one is spared from Foster's sad and forthright commentary on the dismal state of children with respect to the law in the United States today. Attorneys, judges, the police, educators, social workers, and psychiatrists are equally criticized for tunnel vision and for consistent treatment of the child as a thing rather than a person with a voice to be used and to be listened to.

Certain reforms are suggested in the body of the book. The primary one is that independant counsel be provided for all children as they come in contact with the law, be it in a child custody case, a delinquency case, or a struggle with a school board. This recommendation is justified in the following way:

> We make this recommendation not because of any all-out commitment to the adversary system but because we are convinced that the adversary system is here to stay and given this system, independent representation is essential if one is to be heard.

While there is obviously much to be said in support of this position, it is unfortunate that Foster does not grapple with the question of the lawyer's dilemma when his client, conceivably a very young child, instructs him to advocate a course clearly contrary to what he perceives to be the child's best interest.

Another suggestion Foster makes is the creation of an office of public guardian. The public guardian "would have the authority of a surrogate parent and ... would be empowered to consent to welfare, medical, and other services for minors who have left home. This guardian's responsibility would be to serve the best interest of a minor and when proper to preserve confidentiality with reference to matters communicated to him." Theoretically, the public guardian would use the psychological skills of counseling, advice, and persuasion rather than ordering. His emphasis would be on social services rather than on legal rights. This guardian would be of value in situations in which minors need help traditionally offered by parents but the parent-child relationships have broken down. Emancipated minors would be free to use these services or reject them. Again, it is unfortunate that it is not made clear whether Foster intends the public guardian to act in a manner consistent with the child's wishes or, like a traditional guardian, in a manner he feels to be in the child's best interest. For instance, he and the child may well differ as to whether it is "proper" to divulge confidential information. Adoption of this proposal appears to have the potential for creating at least as many problems as it could ever hope to solve.

Foster modestly concludes that he probably overlooked many important interests and rights of children. While this may be true, his work does not lack thoroughness. He also notes that he has emphasized the rights of children rather than their duties. This comes from his personal belief that unless children are treated fairly and unless their rights are respected it is idle to speak down to them about duties and responsibilities.

In this short, well-written monograph Foster manages to cover and effectively summarize important areas of the law as they relate to children. He also discusses in some detail the administration of existing law. He possesses the skill that legal writers are either blessed with or acquire—the superb technical ability to footnote, document, and cite the sources from which conclusions are drawn. The book therefore serves not only as a source of one man's thinking about rights for children but as a reference and text in the area of child forensic psychiatry as well.

If pressed to find fault with the book, I wish that space had allowed more discussion of the education in behavioral science, or lack of it, of law students, judges, and legislators. Such education would enable them to avail themselves more comfortably of those insights the behavioral scientists can offer. While dialogue and interaction between social scientists and legal scientists are increasing, there is still much room for improvement. Foster does cite some theory and opinions of leading behavioral scientists supporting his suggested rights, but I wish space had permitted more.

Bearing in mind that a monograph cannot be all things to all people, this criticism is minor and does not detract from the overall usefulness and value of the text to behavioral scientists and legal personnel dealing with children.

Evaluative Methods in Psychiatric Education, *edited by Hyman L. Muslin, M.D., Robert J. Thurnblad, M.D., Bryce Templeton, M.D., and Christine H. McGuire, M.A. Washington, D.C., American Psychiatric Association, 1974, 220 pp., $10.00.*

This book has a great deal to offer those few psychiatrists who are seriously concerned with conveying what skills they have to younger persons and who are willing to submit to observation, to evaluation, and, perhaps, to change. It is not a book for everybody. It presents information that presumes a considerable knowledge of psychiatric teaching and techniques used in the academic setting. But for those experienced and interested few, a veritable banquet awaits their slow and careful reading.

The book is a compilation of discussions held in 1972 at the Abraham Lincoln School of Medicine in Chicago to update the previous conferences on the subject, at Cornell in 1951 and in Atlanta in 1967. No device seems to have been omitted in this coverage of psychiatric teaching, from simulation of interviews to computer by-play over the cauldron of symptomatology. Even the most experienced professor will gain some insight into the complexities of this, that, or the other technique for teaching, systems to learn what we have taught, and how valid and how reliable our teaching has been.

Like reading the great philosophers, reading each chapter of this book brings a sense of conviction and rightness and sparks enthusiasm to encompass the particular system. When the whole book is read, however, no one system stands out, although none is discounted. Perhaps the reason for this lies in the fact that no matter how esoteric, complex, or mechanized the testing device, psychiatric learning and testing require that a living being participate in a human experience. Only after this experience comes the attempt to codify it for use via infinite numbers, computers, films, questionnaires, or "none of the above."

A good friend of mine, a gynecologist, tells me that the only subject that made much of an impression on him during medical school was psychiatry. He gives as the reason the fact that several times during each week of his psychiatric service, someone talked to him, individually, about what was happening. In no other subject did this occur.

Some skills may simply not yield to quantification. But if one would persist, this book will bring full details and full references to the task. I noted only two slightly negative aspects. One is that only one section concerns itself with any evaluation of the student as he interacts with patients. For much of the text the student is treated in the modern student manner—as an objective peer of the professor who must be taught how to elicit this or that information from patient, movie screen, or computer. Maybe this is how some psychiatrists think, but surely not all. The second point, of no real concern to anyone totally immersed in teaching, is that there is a rapid shift in focus from medical student teaching, psychiatric resident training, and psychoanalytic education. In future volumes I hope these strands could be kept clear because the goals of these three groups are really not the same.

RAYMOND HEADLEE, M.D.

The Prediction of Suicide, *edited by Aaron T. Beck, M.D., Harvey L. P. Resnik, M.D., and Dan J. Lettieri, Ph.D. Bowie, Md., Charles Press, 1974, 249 pp., no price listed.*

This book reflects the increased level of sophistication that has developed over the past decade regarding suicide, our ability to predict it, and, most especially, our ability to prevent it. Formerly, we felt that one could prevent suicide simply by identifying high-risk individuals and publicizing information regarding how persons in trouble could get help. (Of course, we had the same idea about the prevention of venereal disease, drug addiction, and alcoholism.) While the authors of this compendium have not yet looked critically at the possibility that preventive efforts regarding all of the self-destructive behaviors may in fact paradoxically make them increase, they quite adequately bring us up-to-date with the current state of the field.

The book is the result of a conference held in October 1971, under the sponsorship of the Center for Studies of Suicide Prevention of the National Institute of Mental Health. The purpose of the conference was to study the state of the field of suicide prevention and to promote collaborative efforts among researchers. The book is divided into five sections: Historical and Philosophical Perspectives on Classification, The Conceptual Area of Inquiry, Basic Research Issues in Suicide Prevention, Clinical Issues in Suicide Prediction, and Suicide Prediction Scales and Applications.

The first section consists of a single chapter by Joseph Zubin concerning observations on nosological issues in the classification of suicidal behavior. This scholarly chapter sets an admirable tone for the remainder of the book. Zubin describes several scientific models for thinking about suicidal behavior, e.g., the ecological model, the developmental model, the learning theory model, the genetic model, an internal environmental model, and a neurophysiological model. He follows this with a discussion of methodological problems.

The second section is introduced by Alex Pokorny's "A Scheme for Classifying Suicidal Behaviors." He provides a straightforward and understandable consensus for the classification of suicide. Aaron Beck, Dean Schuyler, and Ira Herman discuss developmental scales of suicidal intent in chapter 3.

The third part of the book is introduced by James Diggory's discussion of problems in the use of demographic data and multiple regression methods of analysis. David Lester then describes the use of a variety of standard psychological tests as well as tests specially devised for the prediction of suicide. Jerome A. Motto reports on variables involved in predicting suicide in a large study of inpatients in San Francisco and R.C.B. Aitken describes a method for the measurement of mood by analog.

In the fourth section George Murphy demonstrates his usual careful, critical approach in his discussion of the clinical identification of suicidal risk and Dan Lettieri and Alexis Nehemkis discuss a scale for certifying the mode of death. The team of Robert Litman, Norman Farberow, Carl Wold, and Timothy Brown of Los Angeles report additional efforts to quantify the concept of suicidal lethality. They favor a two-stage screening process.

Dan Lettieri presents a number of suicidal death prediction scales and Avery Weisman and J.W. Worden follow this with a "risk-rescue rating" for the assessment of lethality of suicide attempts in the fifth section. A brief chapter by Robert Sterling-Smith listing the dose of many commonly available drugs required to kill most people follows; one hopes that this chapter is not reproduced for wide dissemination to "do-it-yourselfers." The book concludes with a chapter by William Zung that presents another rating scale for suicide prevention that may be more appealing to the interests of clinical psychiatrists than the ones given earlier in the book.

If one had to recommend a single recent book on suicide, this one would have priority because of the diverse and extensive experience of the participants and because it has excellent references.

The Technique of Psychoanalytic Psychotherapy, vol. 2, *by Robert J. Langs, M.D. New York, N.Y., Jason Aronson, 1974, 527 pp., $15.00.*

Volume 2 of Dr. Langs's *Technique of Psychoanalytic Psychotherapy* continues in encyclopedic detail his presentation of this particular mode of psychotherapy. This volume includes three major sections—Responses to Interventions, The Patient-Therapist Relationship, and The Phases of Psychotherapy. Of the three sections, the one on the patient-therapist relationship is the longest by far, indicating where the author places his primary emphasis. In the sections on responses to interventions and the patient-therapist relationship, Langs considers almost every conceivable situation that may arise to prevent progress or to create impasses in treatment. His instructions for relief of these barriers to progress are clear and straightforward.

The volume is replete with clinical vignettes illustrating every facet of progression, regression, or impasse that may occur. These are drawn mostly from the author's work as supervisor of psychiatric residents; a substantial number are from his own practice. Here, too, Langs does not spare the printed page. In contrast to the usual practice, his vignettes are of sufficient detail to give the reader a genuine sense of the nature of the case and the problem that has arisen.

Dr. Langs's view of psychoanalytic psychotherapy—his close adherence to classical psychoanalytic theory—provides a firm conceptual model for the conduct of therapy. It may seem too rigid to some in its unswerving psychoanalytic stance in respect to investigation, understanding, and resolution. However, one can make a very good argument for the fact that there is more rather than less need now for thoughtful, conceptually sound treatment models.

It seems to me that far too much influence continues to be placed on therapists to do what comes naturally. Implicit in this idea is that there are no genuine models or sound theoretical constructs to follow, except for whatever inner dictates the therapist feels ready to pursue, and that careful, intensive training in the science and art of psychotherapy is unnecessary. Langs demonstrates very well that the psychoanalytic psychotherapist has ample opportunity to be flexible in his work, provided the degree and kind of flexibility chosen is grounded in theory and in observations borne out in practice. Langs carefully documents the misalliances, therapeutic errors, and therapeutic gains that follow directly on the degree of understanding of human behavior that the therapist brings to his work. He highlights in theory and in practice the exquisite nature, subtleties, and nuances of the psychotherapeutic relationship.

It is most impressive to note Langs's dedicated position in promoting independence and autonomy in patients with minimal interference by the therapist. This is in the finest tradition of psychiatry as a humane science. It also accounts for the extensive attention Langs pays to the patient-therapist relationship and all the problems of countertransference that arise so readily and interfere so pointedly by preventing the patient from finding his own way to the inner changes that would allow greater self-fulfillment. Langs makes clear the constant need for self-examination by the therapist in the best interests of the patient. One can only agree with him that there is no substitute for personal analysis to bring light to those parts of the therapist's emotional life which he cannot illuminate and find by himself.

There is not very much in the literature about the opening, middle, and closing phases of psychotherapy. The middle phase, particularly, is so often vague and ambiguous in its boundaries that Langs does a service by elaborating on it. He discusses the middle phase in terms of further delineation of those central issues which are directly related to the unconscious fantasies that are the source of the patient's disability.

The section on the closing phase is also excellent and worthy of special attention because it is here that the least effective work tends to be done. Separations and terminations are the human plague to which no man is immune, patient and therapist alike. Terminations reverberate as much in the therapist as in his patient, and the demand for sensitive understanding of oneself is as important as the understanding of the patient and as the skill that must be brought to bear to bring treatment to a successful close. In this connection, it is interesting to note that so many of the clinical vignettes center around the errors committed at the time of separation and termination.

The only criticism one may make is that there is considerable repetition in the course of the volume. Even this criticism is moderated by the pedagogic value of repetition as useful in learning. This book is a superb reference source, the kind a therapist should have on his shelf for ready reference when confronted with a difficult or puzzling situation in the course of his work.

JAMES MANN, M.D.
Boston, Mass.

The Competent Infant: Research and Commentary, *edited by L. Joseph Stone, Henrietta T. Smith, and Lois B. Murphy. New York, N.Y., Basic Books, 1974, 1,281 pp., $30.00.*

This volume is a must for all students and professional workers concerned with the development of the human infant. The editors, themselves eminent scholars in the field, have selected and edited over 202 studies. They have organized these studies into sections covering individuality in development, prenatal and perinatal development, the capabilities of the newborn, development during the first year, deprivation and enrichment, and the infant as a social being. The various sections have introductory commentaries that are scholarly tours de force. The commentaries point up the significance of the articles chosen, put them in perspective with other work and trends in the field, and review succinctly, thoughtfully, and lucidly the state of the science in each area. Each commentary includes an extensive bibliography covering the relevant literature. There is an excellent index.

In their introduction the editors comment on the previously prevalent professional judgment, which still persists, that the young human infant is an undeveloped, undifferentiated, and primitively responsive organism. The explosion of research in the past 20 years has produced, in the editors' words, a "vast new landscape of knowledge of infancy." This new landscape belies the earlier contention that the human infant is undifferentiated and primitively responsive. Rather, it shows that "from his earliest days, every infant is an active, perceiving, learning, and information-organizing individual," hence the editors' title, *The Competent Infant.*

Even with such a scholarly and authoritative compendium a reviewer is bound by his or her own viewpoint and experience to find some omissions or underemphases. The extensive and pertinent animal studies contain no selections by Schneirla and no mention of his leading coworkers, although this group has made highly significant contributions to the study of behavioral development. The contributions of two leading research child psychiatrists, Chess and Rutter, are given only very brief mention, and Fish is omitted completely. Two articles by Spitz on hospitalism are selected, but none by any of his critics.

However, these are minor criticisms of a work that should become not only a standard reference source but an important original and stimulating contribution to the exploration of this exciting new landscape of knowledge of infant development.

ALEXANDER THOMAS, M.D.
New York, N.Y.

Individual Differences in Children, *edited by Jack C. Westman, M.D. New York, N.Y., John Wiley & Sons, 1973, 335 pp., $15.95.*

This excellent collection of readings expresses Freud's long-neglected assertion that from the beginning, each individual ego is endowed with its own peculiar dispositions and tendencies. This book stresses the fact that constitution is a sum total of structural, functional, and psychological characteristics. The fact that it is compiled of many articles by many authors does not deter from its importance. The most distinguished and interesting workers in the field of child development have been brought together in this volume. The common thread is well maintained and emerges clearly—namely, individual differences in children are important.

The monograph consists of five well-structured and complementary parts. Each is forworded by an excellent summary by Jack Westman that pulls together the essence of the chapters. The first part deals with foundations and structural determinants of early infant behavior as well as with sex differences. The second addresses itself to developmental perspectives and moves from early expression, to the termperament of normal infants, to cognitive structure in latency and adolescence. The third part handles situational perspectives, environmental conditions, and the impact of parent-child relations. It also considers such interesting aspects as birth order and its meaning. The fourth part deals with biological as well as methodological research models. It includes intensive observation of the preschool child and primate personality research. The fifth section deals with the clinical application of measuring infant temperament in pediatric practice. Finally, Westman's summary pulls together all of the material discussed in the book and highlights its significance.

Several articles in this excellent book indicate that we are no longer discussing the prematurely born and maternally deprived child in general terms; we are able to look beyond that frame of reference and see how individual maturational sequences determine future development. Transactions between child and mother are not best observed in an artificially designed testing setting. (Observation is especially useful at the very early stages of development, before the complexity of the cognitive structure of the person emerges.) In addition to participant observation and direct study of early life, we are able to link behavioral observations with behavioral determinants. Moreover, it is now possible to make statements about observed behavior in a developmental framework and connect both intrapsychic and manifest behavioral phenomena over time.

Each part of this book is preceded by a well-selected quote; Charles Darwin's seems to express the spirit of the whole work:

> No two individuals of the same race are quite alike. We may compare millions of faces, and each will be distinct.

I strongly recommend this monograph to all professionals who are ready to broaden their scope and allow new ideas to make their proper impact.

LEON TEC, M.D.
Norwalk, Conn.

Mental Illness and the Economy, *by M. Harvey Brenner. Cambridge, Mass., Harvard University Press, 1973, 281 pp., $15.00.*

Dr. Brenner has produced systematic data on the relationship between mental illness and economic variables from which he concludes that a major paradigmatic shift in perspective may be essential. He suggests that the problems of persons who have been mentally hospitalized as a result of downward economic mobility are usually the result not of their own incompetence but of large-scale economic instability in the society—especially the instability manifested in short-term downturns.

Is Brenner acceding to an ecological fallacy or is he attempting to alert the psychiatric profession to a more sensitive stance toward environmental variables? He states,

> These findings raise questions about the utility of therapies that do not take into account disturbances in the patients' social environment which may have made treatment necessary. (p. xi)

Unfortunately, Brenner's description of the statistical procedures employed may be too brief to assess the validity of the methodology. A technical appendix in a later edition would complement the lucid outline of his approach found in the introduction and in the supportive bibliographical citations throughout this text.

Several of the findings are disturbing. Married persons show the most reliable inverse relationship between admissions to mental hospitals and economic change, whereas groups of single persons display only a moderately reliable relation. Farmers, laborers, and salesmen appear to be most vulnerable. Economic downturns occurring during periods of large-scale prosperity produce enormous increases in mental health treatment. Further research is required to determine whether or not the loss of employment, income, or both is correlated with an increase in the incidence of mental illness.

This study offers many leads to specific items of research on the relationship between the economy and mental illness. Policy makers concerned with the economy or mental health desire

such research and need critiques of Brenner's findings because they may be continually faced with the decline of economic institutions and the growth of social and health industries designed to deal with a variety of problems related to the decline.

The psychiatric profession cannot afford to ignore Brenner's readable and scholarly study. It must debate his contention that American clinicians involved in psychiatric care operate under a set of values and beliefs that are probably antithetical to the perspective of this study. Is the transition from Brenner's finding about the relationship of the economy and mental illness to his judgment about the profession justified? Is Brenner's macro viewpoint irreconcilable with the micro approach of clinicians? Brenner's analysis is not a definitive work but a promising beginning; the clinicians have yet to be heard.

HENRY A. FOLEY, PH.D.
Rockville, Md.

The Diphenylbutylpiperidines. First North American Symposium, 1972, *edited by André Villeneuve, M.D., and Jean-Marc Bordeleau, M.D. Québec, Canada, Les Presses de l'Université Laval, 1973, 134 pp., no price listed (paper).*

Interest in the long-acting oral and injectable neuroleptics has mushroomed worldwide in recent years. This interest has been sparked by the advent of a variety of these agents—seven injectables and three orals (pimozide, penfluridol, and pipothiazine)—and by the testimony of investigators about their efficacy and safety as well as the impact they may have on the economics of mental health care.

This book consists of the papers presented in Montreal in 1972 at the first North American symposium on the diphenylbutylpiperidines, a new series of neuroleptics synthesized by Paul Janssen. Dr. Janssen is the "father" of the butyrophenones and many other drugs active in the central nervous system. To date, only three of the diphenylbutylpiperidines have been tested clinically: the oral pimozide, which has a duration of action of over 24 hours and hence is administered only once daily; penfluridol, which has the longest duration of action of any known oral neuroleptic and is usually administered only once every 5 to 10 days; and the long-acting injectable fluspirilene, which has an average duration of action of 7 days and is usually administered once a week. Pimozide is marketed outside the United States under the trade name Orap. The commercial introduction of all three substances worldwide is probably only a matter of time.

The opening chapter makes up almost one-third of this monograph. It is an excellent review of the chemistry and pharmacology of long-acting nueroleptics by Dr. Janssen. The remainder of the book consists of relatively short chapters reporting on the results of open and double-blind controlled studies of pimozide and fluspirilene by different Canadian clinical investigators. One of these reports has been printed previously under a different title (1). Each of these reports verifies again the efficacy and safety of pimozide and fluspirilene in the maintenance treatment of chronic psychotic patients, especially schizophrenic patients.

Although there is enough information on pimozide and fluspirilene in this short book that its purpose is fulfilled, it must be stated that anyone who wants more than a modicum of knowledge about these compounds must turn to other sources of data. In my judgment, psychiatrists should become familiar with the long-acting neuroleptics; there is no doubt that they will play an ever-increasing role in drug therapy for psychoses.

Family Psychiatry for Child Psychiatrists, *by John G. Howells. Ipswich, England, Institute of Family Psychiatry, 1972, 50 pp., 50 pence (paper).*

This excellent little monograph is a concise description of the organization and operation of child psychiatric services in Great Britain.

The title reflects the author's conviction that the child is best treated by an approach that takes the family as the patient, along with the corollary that child or family psychiatric services are best located in hospital settings, close to parallel psychiatric services for adults. The presentation is authoritative, straightforward, without much discussion of alternative points of view, but balanced and sensible. (There are many references to the way things are done at Ipswich.)

American readers will find much of interest here. Psychiatric services for children in Great Britain have been coping with the task of serving an entire population under the National Health Service program for 25 years. The experience has led to some conclusions about coverage, types of services, and the way these services should relate to other services for children such as schools, medical services, and family practitioners.

Support, Innovation, and Autonomy: Tavistock Clinic Golden Jubilee Papers, *edited by Robert Gosling. New York, N.Y., Barnes & Noble Books (Harper & Row, distributor), 1974, 289 pp., $16.50.*

Many of the papers collected in this book were read on the occasion of the golden jubilee of the Tavistock Clinic. They are all skillfully interrelated and deal with the development of autonomy in the individual and the antecedent support and innovative steps essential to the development of a genuine personal autonomy.

Dr. Gosling has given us a magnificent example of competent editing. Unlike the usual collections of papers loosely held together in a volume of this sort, his frequent editorial comments and careful selection of topics and styles provide the continuity usually seen only in books by a single author. The authors of the papers, too numerous to mention by name, are outstanding authorities who demonstrate considerable ability in presenting their topics succinctly and with integration.

An introduction by the editor describes his concepts of support and innovation as they are operative in all phases of society from the smallest unit, the family, to such highly complex units as industry, schools, and hospitals.

The early roots of autonomy in childhood are considered in papers on self-reliance and substitute mothering during family crises. The impairment of autonomy in a child whose mother is physically present but emotionally unavailable is well documented.

Two dramatic papers, one on dependence and independence in an institution for incurable patients and the other on attach-

ment and autonomy at the end of life, provide insight into the role of autonomy in people who are severely challenged by immutable personal crises.

Autonomy is also impaired in psychological dislocation, as in the case of a conflicted marriage relationship. Psychotherapeutic intervention in such a marriage is presented by case study material. Therapeutic factors in analytically oriented brief psychotherapy are also considered.

The final section of the book discusses the practical exercise of autonomy in various aspects of employment (i.e., absenteeism, casualties, etc.), in personality factors involved in joining a new group, in family enabling processes in dual-career families, and in the roles of silence in intrafamilial hostility.

There is much to be gained from reading this book. In no other volume have I ever seen the concept of the development of autonomy, its antecedents, its modifications within the family and by therapy, and its role in mature life so well presented. It is recommended reading for psychiatrists and other sophisticated students of mental health.

LUDWIG M. FRANK, M.D.
West Hartford, Conn.

The Psychoanalytic Study of the Child, vol. 28, *edited by Ruth S. Eissler, M.D., Anna Freud, LL.D., D.Sc., Marianne Kris, M.D., and Albert J. Solnit, M.D. New Haven, Conn., Yale University Press, 1973, 511 pp., $15.00.*

Since it began publication in 1945, this annual has been a keystone in the psychoanalytic literature. Its policy is and has been to present research findings from the psychoanalytic treatment and observation of children as well as theoretical papers pertaining especially to the genetic point of view, which pertains to the origins and development of psychological phenomena in the individual (1). Psychoanalytic metapsychology consists of the set of essential assumptions on which psychoanalytic theory is based. It includes five points of view: the dynamic, the economic, the structural, the genetic, and the adaptive.

This issue is in its usual format, with papers in four categories: Aspects of Normal and Pathological Development, Clinical Contributions, Contributions to Psychoanalytic Theory, and Applications of Psychoanalysis.

The first section has articles based on direct study of children through treatment and/or observation. There is an exploration of the preoedipal infant-father relationship and a reexamination of the impact of the primal scene on child development.

The findings of a psychodynamic study of "gifted underachievers," if confirmed, will have important implications for early childhood education, particularly education that occurs within the family. An article on childhood psychosis is based on the treatment of a four-year-old whose struggle for separation and individuation was reflected in the vicissitudes of her bladder and bowel functioning. Another, on the infantile fetish, scrutinizes the classical psychoanalytic theory of fetishism through observation of 35 infants in a research nursery.

The clinical contributions are cogent and well written, beginning with a report of the analysis of the son of a refugee and how that reality colored the form of his neurosis. Another paper examines the similarities and differences between separation-individuation in early childhood and the adolescent's struggle for genital primacy and object removal. Others report on the effect of rape on children, the efficacy of preventive analysis following trauma, the incredible technical difficulties of analyzing a disturbed deaf-mute child, and the place of "preparatory educational help" for children who are initially unanalyzable.

The material in the theory section, aside from being esoteric to the interests of nonanalysts, is composed of four articles that are uneven in the extent to which they advance theory building in psychoanalysis. There is a somewhat abstruse essay on interpretation from the point of view of semantics that contains the often-repeated caution that in analysis we interpret in the language of the present affects and experiences of the past that had very different verbal representation or none at all.

A paper on the concept of aggression attempts to solve the very old problem of explaining aggression without resorting to the instinct concept. The approach is to assume that both aggression and libido derive from an inborn "automatic flight mechanism" whose direction is determined by the environment. An article on acting out as a character trait is not really theoretical but actually a rather good paper on technique. One on attachment to painful feelings and the negative therapeutic reaction is interesting as a clinical report. Its theoretical ideas are not convincingly different from those offered for masochism in the past, although the author attempts to put them on a broader base.

The chapter on applications of analysis has a report on psychoanalytic research into the intellectual functioning of black children reared in a ghetto. The findings are modest and are in line with prevailing expectations. There is a study of a child's game called "jinx" and a delightful view into the lives and creativity of A.E. Housman and René Magritte in a paper titled "The Image of the Lost Parent."

Eysenck on Extraversion, *by H.J. Eysenck. New York, N.Y., Halsted Press (John Wiley & Sons), 1973, 174 pp., $4.95 (paper).*

In the historical introduction of this book Eysenck notes that he resurrected the concept of extraversion-introversion and in so doing created somewhat of a stir among psychologists interested in personality. The concept had been popularized by C.G. Jung, although it did not originate with him. However, like many other concepts unsupported by empirical evidence, it fell into general disrepute in academic circles.

Eysenck's use of the terms extraversion and introversion is not identical to that of Jung. Rather, it represents an attempt to link together the neural and cognitive control theories of functioning. Klein and associates (1) presented an excellent evaluation of Eysenck's analysis of extraversion-introversion in 1967.

Eysenck's book consists of research articles previously published elsewhere. It is a book of readings, a smaller version of a three-volume work published in 1971 (2). It is arranged into three parts covering the nature of extraversion, extraversion and social behavior, and the experimental study of extraversion. Each paper is a scientific study of a particular dimension of extraversion. The reader will find as he reads each chapter that he gets not only a greater appreciation of the concept of extraversion but also a greater insight into the man, scientist, and scholar Hans Jurgen Eysenck.

Extraversion as Eysenck envisions it has two aspects, the phenotypical and the genotypical. His concern is not simply to classify behavior in terms of everyday activity but to understand it in terms of inherited characteristics, particularly the inherited disposition of the central nervous system. The reader is carefully brought through general principles and methods of personality description, classification, and diagnosis. Gradually he is introduced to an understanding of extraversion in terms of a concept and a factor. The rigid scientific method is ever present throughout the book. Eysenck does not let the reader forget that he is a scientist as he develops hypotheses and subjects them to experimental scrutiny with the assistance of statistical techniques, the favored of which is factor analysis.

Undoubtedly, certain chapters will appeal more to some than to others. However, the heuristic quality of this book is irresistible, subtly encouraging the reader to test the hypotheses generated. For this alone the book is well worth having in one's library.

Practical Aspects of Mental Health Consultation, *edited by Jack Zusman, M.D., and David L. Davidson, M.D. Springfield, Ill., Charles C Thomas, 1972, 152 pp., $6.75.*

The product of a conference on community psychiatry held at the State University of New York, Buffalo, in 1970, this volume presents most of the papers given at the seminar concerned with the subject of mental health consultation.

The social importance of this field is stressed. The writers focus on the potentially broad impact of mental health consultation on issues of mental health prophylaxis and on community attitudes toward the theory and practice of mental health care as well as the enormous challenge and complexity of developing an effective process of consultation. The great need for further information and experience and the ultimate development of a well-defined and systematic body of knowledge is acknowledged; the papers compiled in this book are presented as another step in this direction.

The book is subdivided into sections dealing with particular aspects of mental health consultation. These include, among others, the theory of consultation, the practical aspects of the consultation process, the training of consultants, and discussion of the distinctions among consultation, supervision, and psychotherapy.

The interest and value of the volume are greatly enhanced by the multidisciplinary background of its contributors. The fields of psychiatry, psychology, social work, education, and nursing are represented. The purpose and process of consultation are discussed in a stimulating manner from a number of different perspectives—from the point of view of the consultee as well as the consultant. As the title suggests, much of the material is highly practical and would be valuable to individuals involved in the practice of mental health consultation.

DAVID W. WYCKOFF, M.D.
Newtown, Conn.

Assessment of Sexual Function: A Guide to Interviewing, *by the Group for the Advancement of Psychiatry Committee on Medical Education. New York, N.Y., Jason Aronson, 1974, 92 pp., $7.50.*

This GAP report is designed as a "manual for the practicing physician, the medical student, and others in the health field." Emphasizing an open-ended, semistructured interviewing technique as the sine qua non of eliciting information from the patient, the guide first attends to the interviewer, his or her attitudes, and the setting of the interview.

Neither the initial interview nor the specific questions identified in Appendix A ("Topics Covered in a Sexual History") and Appendix B ("Sexual Performance Evaluation") is intended to communicate that the taking of a sexual history should be a specific form of interrogation or relationship separate from the rest of the interview. Rather, the skillful and experienced interviewer will incorporate and/or adapt many of the suggestions offered to his or her unique interview style.

In subsequent chapters, the guide is addressed to specific sexual problems of the married couple; the sexual functioning of children, adolescents, "other" single persons, and older people; and covert sexual problems presenting symptoms relating to other organ systems and to depression.

Manuals of the how-to-do-it sort invariably engender mixed reactions in the reader. They tend to appear superficial, naïve, spotty in coverage of a broad subject, and dogmatic despite apologies and protests to the contrary. On the other hand, their strength lies in directness and succinctness.

A specific criticism of this book is that despite the fact that it was prepared by psychiatrists, there is little that is "psychological" in its approach. It is a bit too mechanistic. Patients often do not present sexual problems as such; "straightforward" history taking may increase their resistance. Sexual problems may often remain unelicited until the third or fourth interview and occasionally not until months after the development of a patient-physician relationship.

Paradoxically, there are some valuable pointers in this book that the sophisticated interviewer may add to his or her interview, while the unsophisticate may use it too directly and mechanistically. In summary, whereas it is a useful guide for the physician, it is not sensitive enough psychologically to have warranted preparation by psychiatrists. A bibliography directing the reader to more extensive primary sources rather than to other manuals would be a valuable addition.

CHASE PATTERSON KIMBALL, M.D.
Chicago, Ill.

A Psychoanalytic Study of the Psychoses, *by Thomas Freeman, M.D. New York, N.Y., International Universities Press, 1973, 328 pp., $10.00.*

There are two psychoanalytic models for psychosis, for schizophrenia in particular, the deficit model and the defense model. The first corresponds to what London (1) called Freud's specific theory. According to this theory psychosis is clearly separated from neurosis. The defense model corresponds to the unitary theory, which postulates that there are intrapsychic conflicts and motives common to neurosis and psychosis. Both models are consistent with etiological theories of constitutional weakness, genetic anomaly, and theories of schizophrenogenic mothering or severe trauma.

In the deficit model, there is a deficiency state that consists of

a failure to maintain unconscious mental representations. Freud originally described this as a shift in libidinal investment away from object representations to the self 15 years before he postulated the structural theory of an organized ego.

It is unfortunate that this concept, the disruption of the mental organization of memory traces that represent internalization and integration of experiences, has until recently been couched in terms of psychic energy and outdated formulations of narcissism. The nonautonomous part of the ego is built from internalized bits and pieces of experiences, including drives, defenses, anxiety and other affects, and, especially, the coping mechanisms and regulatory functions of the mother. The psychological weakness in the capacity to organize and maintain internalized self and object representations under stress is the ego deficit.

The defense model is based on the theories of conflict, signal anxiety, defense, and regression. Due to innate or experiential factors, developmental disturbances in the psychotic are earlier and more severe than in the neurotic. Consequently, greater conflict over aggression occurs. The defensive process is characterized by greater regression. In the heirarchy of defenses against anxiety and impulse, the psychotic employs such primitive measures as denial, disavowal, and ego splitting. The ego is not able to maintain secondary autonomies against the intense conflict and regression and undergoes regressive alteration in the service of defense.

In this book Dr. Freeman applies the profile schema developed at Anna Freud's child therapy clinic at Hampstead to the fuller understanding of psychotic patients. There is a useful intermingling of theoretical concepts with a wide variety of illustrative case reports. The author's position is an amalgam of the deficit and the defense theoretical models. Unfortunately, the integration is incomplete because Freeman couches the deficit concept in the older framework of cathectic shifts from object to self. He ignores such modern concepts as Jacobson's self-object representations and Mahler's separation-individuation phases.

While profile schemas enable the investigator to compare one patient to another or to evaluate progress in a given patient, I question whether an adult profile provides more than an elaborate systematic mental status. The Hampstead profile was developed specifically for children because it was found that pathology in childhood was best assessed in terms of factors interfering with normal forward development rather than in terms of severity of symptoms. For this reason, profile schemas have limited application to adult pathology.

ROBERT D. GILLMAN, M.D.
Washington, D.C.

The Diagnosis and Management of Depression, *by Aaron T. Beck, M.D. Philadelphia, Pa., University of Pennsylvania Press, 1973, 147 pp., $8.50.*

De gustibus non est disputandum. Some readers prefer encyclopedic tomes that cite every paper in the literature. Other tastes run to the thin monograph that covers a topic concisely. Aaron Beck can do both. This book is an abridged and updated version of his comprehensive volume *Depression: Causes and Treatment* (1).

In a well-organized, lucid, and useful manner, Beck has given us a book that will be helpful to medical students, psychiatric residents, and mental health practitioners. He highlights the four major issues on the topic of depression: 1) whether depression is an exaggeration of a normal mood or is qualitatively different; 2) whether depression is a disease or a symptom; 3) whether depression is a reaction or a disease; and 4) whether depression is caused by psychological stress or biological derangement. He defines the basic symptoms as specific mood changes, negative self-concept, regressive and self-punitive wishes, vegetative changes, and change in activity level.

In chapter 2 Beck reviews the symptoms of depression, offering not only a review of the existing literature but the results of his own study of over 1,000 patients. The third chapter is about course and prognosis, reviewing whether the illness is episodic or cyclical and what are the prospects for recovery, the duration of attacks, the likelihood of recurrence, and the risk of suicide. The fourth chapter concerns classification and various dualisms about depression, e.g., is depression endogenous or exogenous, autonomic or reactive, agitated or retarded, psychotic or neurotic?

The neurotic-psychotic dualism is the subject of the fifth chapter. Beck feels that no specific signs or symptoms other than delusions are able to distinguish the two. The more severe the depression, the more likely it is to be called psychotic; the differences are quantitative. The chapter on pharmacotherapy reviews 232 studies. It is especially helpful on the subjects of management of side effects and the differences between the effects of antidepressants and electroconvulsive therapy (ECT). The seventh chapter focuses specifically on ECT and reviews the evidence that many patients who do not respond to medication will improve with ECT. The chapter on psychotherapy gives the schema of Beck's own approach, which he calls "cognitive psychotherapy."

There is an excellent general bibliography. The chapter on pharmacotherapy, unlike the other chapters, includes a complete literature review. Dr. Beck explains that this material needs to be updated; for that reason the recent literature on antidepressants is covered thoroughly. Chapters are arranged with logical subheadings, which makes it easy for the clinician to find answers to specific questions. While it is difficult to fault this book, one might criticize the fact that there is little about hospital management of depressed patients. There is also no comment on the family of the depressed patient or on working with the patient in group or family psychotherapy. The book also suffers from the lack of a general index.

In spite of these minor criticisms, the book is a very useful addition to the literature and will be of help to the clinician who treats depressed patients.

Dying and Dignity: The Meaning and Control of a Personal Death, *by Melvin J. Krant, M.D. Springfield, Ill., Charles C Thomas, 1974, 154 pp. $7.95; $5.95 (paper).*

This small volume on dying, which represents the author's personal viewpoint, is intended for the general public. As such it may prove a useful catalyst of public debate. Dr. Krant notes

that the circumstances surrounding death have been changing. Most people die in their old age and in hospitals, where the precise timing and manner of their dying are under the ever increasing control of physicians. Krant feels that because we see less of death we are less prepared for it and that because people die in institutional settings they suffer their isolating and dehumanizing influences. Krant also believes that modern technology is abused by physicians who sustain lives long after they have lost their human qualities. He views the cost of this in human resources and dignity as enormous.

Dr. Krant urges more open communication with dying patients; he feels that greater responsibility for decision making should be placed in the hands of these patients and their families. This calls for a less rigid and authoritarian approach on the part of many physicians. He advocates more personal and flexible institutional care that would involve greater teamwork and continuity on the part of professionals. In his view, a patient's request for termination of his life should be given serious consideration. While he favors active euthanasia, his words are appropriately cautious.

Although somewhat repetitious, this book is simply and clearly written. Some parts lack the freshness provided in other sections by clinical illustrations. While the author has furnished no final answers—nor could he—he has increased our awareness and furthered our debate of these important issues. The book offers an overview of the subject that might prove useful to students enrolled in courses on death and dying.

RUSSELL NOYES, M.D.
Iowa City, Iowa

A Second Look at Life. Transplantation and Dialysis Patients: Their Own Stories, *edited by Felix T. Rapaport, M.D. New York, N.Y., Grune & Stratton, 1973, 91 pp., $5.95.*

This book is the result of a symposium held in September 1972 attended by kidney transplant and dialysis patients from all over the United States. Some of the presentations given at this symposium were published as a journal issue of *Transplantation Proceedings* in June 1973. These have now been republished in the form of this book.

The major purpose of the book as indicated by its editor is to bring renewed hope, faith, and confidence to patients with kidney disease. Only as a secondary aim is it hoped that the book will be useful to professionals in providing insight into the social, psychological, and ethical problems of this particular patient group. The book has three basic parts: 1) a series of three- to four-page testimonials from 15 patients, 2) another series of short vignettes from 6 transplant donors, and 3) seven articles by professionals on the ethics, costs, and psychology of transplantation.

In terms of its primary goal, which is one of public relations, the book vividly illustrates to potential patients, federal funders, and referring physicians that kidney transplantation can rehabilitate patients and create many psychological rewards for patients and their families. Public health journals and referring physicians have criticized the use of public funds for the expensive technology of transplantation, particularly on the grounds that these patients are not well rehabilitated and are psychological cripples.

The testimonials in this book challenge the idea that kidney transplantation is a traumatic experiment rather than a viable therapy. The more prosaic statistics also challenge the criticisms: 72 percent of patients receiving kidneys from related donors have functioning grafts at the end of two years, as do 46 percent of patients receiving cadaver kidneys. Running through the stories is the theme of rebirth, of an exhilarating new life in which existence is more fully experienced after a close call with death and after a successful transplant.

Many of the patients had received their transplants 4, 6, 7, and in one case 13 years before the symposium. Furthermore, the related donors generally regarded the experience as a highly positive one. Parents who had faced the decision of allowing their child to die or taking the risk of transplantation and donation exulted in their active, healthy, growing children.

In terms of educating the professional, this volume may be particularly useful for those with little experience with transplant patients. The case histories are typical of patients who have successful courses. The horrors of being ill with terminal kidney disease are described with more vividness than any outsider could muster. For those professionals with more experience with this type of patient, other sources might be more useful in outlining the psychiatric problems of the patients, their families, and the staff (e.g., the February 1971 issue of *Seminars in Psychiatry*, titled "Psychiatric Aspects of Organ Transplantation"). Particularly interesting in this book are the articles by Douglas on the costs of transplantation, by Schreiner and Riteris on ethical considerations, and by Sadler on living unrelated donors.

There are some biases in the book that should be noted. First, there is a definite bias toward transplantation as opposed to dialysis. Proponents of dialysis might take issue with this. Second, the stories seem to emphasize only the successful aspects of posttransplant life. It is true that transplantation is most frequently successful. However, for the minority of patients for whom transplantation is unsuccessful, stress can be extreme. Some of the ordinary "successful" patients have problems that are almost untouched in these stories, although they were discussed at the symposium, e.g., the cushingoid "moonface," suicidal thoughts, and the side effects of cataracts, acne, and bone decalcification.

It is interesting that the following case history presented at the symposium is omitted from the book: a wife related the story of her husband's fourth transplant and his multiple complications, which included a cardiac arrest, a lung collapse, and a perforated abdomen. Also omitted is the careful documentation of risks to the donor presented by Dr. John Bergen at the symposium and any discussion of donor ambivalence.

In summary, this book makes excellent and interesting reading, particularly for those who are unaware of the successes of kidney transplantation and for those who are facing this therapy. The view presented is a real one, but somewhat biased in an optimistic direction. For the psychiatrist or social worker who wishes to help these patients, pretransplant stresses are more clearly depicted than posttransplant stresses.

ROBERTA G. SIMMONS, PH.D.
Minneapolis, Minn.

The Mind Possessed: A Physiology of Possession, Mysticism and Faith Healing, *by William Sargant. Philadelphia, Pa., J.B. Lippincott Co., 1974, 203 pp., $7.95.*

This most interesting book represents a continuation of Sargant's earlier work, *Battle for the Mind* (1), offering further documentation of possession phenomena to support his theory of brainwashing.

Sargant suggests that methods of thought reform, religious conversion, and psychotherapy all facilitate change by producing excessive cortical excitation, emotional exhaustion, and

states of reduced resistance, which, in turn, increase the patient's chances of being converted to new points of view. According to Sargant, such emotion-arousing activity, which is common in a variety of psychiatric settings as well as in the ritualistic practices typical of developed and developing societies, reduces resistance to change by freeing the individual from neurotic symptoms while introducing new ideals.

Sargant's methodical zeal to explore the phenomena of possession has taken him to the Sudan, Zambia, Nigeria, Dahomey, Brazil, Trinidad, Jamaica, Barbados, Haiti, and Appalachia. He has witnessed Zar possession, Macumba rites, voodoo, snake-handling cults, and revivalist sects. He recounts his experiences and observations with gusto in this book.

The array of accounts is impressive. Equally impressive is Sargant's effort to demonstrate the link between possession states and mesmerism, hypnosis, the effects of severe stress on the battlefield, sexual orgasm, and the use of drugs. Some may argue that the attempt to unify such dissimilar phenomena in terms of a single theory of nervous system excitation based on Pavlovian principles leaves little room for other theoretical considerations or for an examination of the subtle interrelationships among particular ceremonies, cultural contexts, and personality patterns. However, Sargant's orientation serves a definite purpose in providing us with a clearly stated perspective from which to examine such diverse phenomena.

We need to learn more about the differences in electroencephalographic response patterns as well as the role of metabolism in facilitating entry into such unusual mental states. For example, Adolf Meyer has suggested that the drug rhythms in some native rituals may induce states of possession by producing an auditory driving effect on the resting rhythms of the brain similar to the phenomenon of photic driving seen in photic epilepsy.

While Sargant neglects to consider the relationship between the common elements of possession phenomena and the social, cultural, and historical traditions in which they develop, he is to be commended for providing us with an impressive journalistic-scientific account in the tradition of many well-traveled English physicians. His book is most stimulating and—as always with Dr. Sargant—most provocative.

Problem Drinking Among American Men. Monographs of the Rutgers Center of Alcohol Studies 7, *by Don Cahalan and Robin Room. New Brunswick, N.J., Rutgers Center of Alcohol Studies, 1974, 258 pp., $12.50.*

Problem Drinkers Seeking Treatment. Monographs of the Rutgers Center of Alcohol Studies 8, *by Eileen M. Corrigan. New Brunswick, N.J., Rutgers Center of Alcohol Studies, 1974, 79 pp., $6.00.*

These monographs are part of a series of 10 published by the Rutgers Center of Alcohol Studies. Other monographs in the series include *Alcohol and the Jews, Alcohol in Italian Culture, Drinking Among Teen-Agers,* and *The African Beer Gardens of Bulawayo.*

The subjects of *Problem Drinking Among American Men* are men aged 21 to 59 with drinking problems, drawn from two national surveys and from a community study in San Francisco. Cahalan and Room examine in detail the drinking habits of these men, the problems they experience as a result of drinking, and their socioeconomic characteristics.

The purpose of the study is to get a better idea of the epidemiology of alcoholism in the United States in an effort to understand, control, and perhaps prevent problem drinking in our society. The study itself is statistically involved and difficult to follow because of the complex variables that have to be considered in any analysis of drinking patterns.

The findings are what might be expected. In general, the men surveyed usually had more than one problem caused by their drinking. These problems ranged in increasing frequency and severity from troubles with the police, belligerency with others, job and financial problems, health problems, and quarrels with their wives to psychological dependency. Tangible consequences and problems related to heavy drinking occurred most often in the younger men, the poor, the ethnically disadvantaged, those with unstable work and marital records, and those exposed to heavy social drinking. It is not made clear whether these factors are causes or effects of heavy drinking.

The early life histories of these men indicate an unstable home environment, an alcoholic father, youthful acting out or impulsivity, alienation, and lack of ego resiliency during childhood.

Environmental factors associated with alcoholism are exposure to heavy social drinking, a rural background (especially from temperance-minded and "dry" communities), and a disadvantaged background.

Cahalan and Room do not come to any firm conclusions, but they do suggest further studies to determine more precisely the etiology of alcoholism, especially from the cultural standpoint. The important finding of this extensive study is that more attention should be given to the younger group of heavy-drinking American men. This group is the major progenitor of future alcoholism.

The eighth monograph in the Rutgers series, *Problem Drinkers Seeking Treatment,* is a unique and important contribution. Corrigan reports what happens to alcoholics who telephone, or have others telephone, an information or referral service for help. Three hundred such calls to the Information Bureau of the Community Council of Greater New York were followed up.

The findings show that this information and referral service does in fact perform a real service. Of the total number of callers, 54 percent of those for whom someone else called reached treatment, compared with 68 percent of those who made the call themselves. This suggests that alcoholics should be encouraged to initiate inquiries themselves.

Learning of the service through physicians, hospitals, or social agencies resulted in greater use of the resource. Subway, newspaper, and telephone-book notices were next in effectiveness and radio and television spots were least effective. More clients reached treatment when the referral center actively helped to arrange appointments. More than half of the clients who contacted the bureau got into and remained in treatment for at least 45 days.

Unfortunately, the treatment received by these clients often left much to be desired. The main treatment resources were general hospitals where the attention given alcoholics was often perfunctory and little effort was given to aftercare. About one-half of the clients referred to hospitals dropped out soon after the initial hospital contact.

Corrigan stresses the need for better alcoholism treatment programs in hospitals if the efforts of referral agencies are not to be wasted and the motivation of clients dissipated. She urges

referral sources to become more active in evaluating and upgrading treatment facilities in the community. Better treatment should be provided for those alcoholics seeking help.

Seattle, Wash.

Comparative Psychiatry: A Theoretical Framework, *by P.M. Yap, edited by M.P. Lau and A.B. Stokes. Buffalo, N.Y., University of Toronto Press, 1974, 110 pp., $10.00.*

Pow Meng Yap, one of the pioneers in Oriental cultural psychiatry, left his position at the University of Hong Kong in June 1971 to take up the newly created Chair of Transcultural Psychiatry at the University of Toronto. He died suddenly in November 1971.

This work, which has been edited and revised by two of his colleagues in Toronto, is a presentation of the knowledge Yap had accumulated over many years as well as a memento to his lifelong dedication to Far Eastern psychiatry. The book is titled *Comparative Psychiatry*, in contrast to "comparative psychiatric sociology." Yap defines the former as "that branch of transcultural psychiatry which is concerned mainly with clinical presentation [of mental illness] in different cultural settings."

The book is an attempt to establish a theoretical framework within which all the facts that we possess about mental disorder anywhere in the world can be encompassed and interrelated. By studying similarities and differences in the comparative phenomenology of illnesses transculturally, Yap sought to discover universal regularities of form and process. He aimed at understanding biopsychological and sociocultural variables in psychiatric illness. His wide approach encompasses such issues as the harmony of biological and sociological viewpoints, the differentiation of illness from deviancy, the problems of the sick role, communal belief, and the relating of brain to mind and thence to social gestalt. To attain these objectives he tries in this book to synthesize ideas drawn from such fields as psychoanalysis, general systems theory, neural theories, learning theory, ethology, role theory, and folk customs.

Yap's conclusions may be summarized as follows: 1) abnormal functioning is one extreme of a continuum of behavior grading into the normal at the other extreme; 2) a pattern of behavior must be regarded as abnormal even if it is manifested or supported by a large subgroup of a community; 3) there is a basic commonality in the mental diseases found in different cultural settings; and 4) judgment should be drawn from one of two levels, biological or sociopsychological, depending on which is more meaningful.

Chapter 8, "Nosological Aspects of the Culture-Bound Syndromes," introduces a practical note. Such disorders as koro, susto, latah, and amok are dealt with. Yap offers a classification of these syndromes. While they may manifest themselves in a highly stereotyped form when acute, their symptomatology may change with changes in society, its mores, and Zeitgeist. "Thus," he states, "the study of comparative psychiatry as an asynchronic discipline leads us theoretically to problems of historical change." He believed that treatment of these syndromes consists of shared sentiments and customary patterns of action, which are intimately bound up with the structure and content of the illness treated.

Yap's book is rich in content but heavy in style. It is instructive, interesting, and stimulating. It shows its author's erudition. However, Yap's very wide approach inevitably results in misrepresentation in some areas and oversimplification in others. Had he lived longer, Yap might have revised some of his formulations. He states in the preface, "This monograph is more an essay than a fully argued scientific treatise, but the subject demands a synthetic, many-disciplined approach which at times may appear superficial if not idiosyncratic to the specialist in a particular field."

E.D. WITTKOWER, M.D.
Montreal, Que., Canada

The Arctic Hysterias of the North Alaskan Eskimo, *by Edward F. Foulks. Washington, D.C., American Anthropological Association, 1972, 159 pp., $6.00; $3.00 (paper).*

"Arctic hysteria," which is presumably an exotic form of mental illness, was reported by some of the early explorers and ethnographers of Canada, Alaska, and northern Greenland. In the field of cross-cultural psychiatry it has come to be thought of as a culture-specific mental illness. This means it has been put forth as a unique pattern of behavior understandable only in terms of Eskimo culture. Interest in this phenomenon has been heightened by the fact that the Museum of Natural History, Washington, D.C., exhibits a collection of pictures from Perry's 1907 expedition that show an Eskimo woman going through an episode involving her mimicking local animals, falling into a convulsion, and demonstrating carpopedal spasms, body trembling, and exhaustion.

Although a number of people have tried to determine the pattern and prevalence of Arctic hysteria from the existing data and have developed theories to account for it, the effort reported in this new book is, as far as I know, the only all-out search for the phenomenon in contemporary Eskimo society. The author is a psychiatrist; this volume is the end product of his further training as an anthropologist. His goal was to test the hypothesis that Arctic hysteria can best be understood from an interdisciplinary perspective. The search and the goal could hardly be more laudable, but I suspect that the value of the endeavor is mainly unintended.

The search revealed that the Arctic hysterias are rare (10 cases were found among the 11,000 Innuit Eskimos of northern Alaska). The few people said to suffer from the disorder were exceedingly heterogeneous: "Several subjects had epilepsy; several were diagnosed as schizophrenic; most had low normal serum calcium levels; and one had hypomagnesemia and possible alcoholism" (p. 117).

The fact that arctic hysterias are uncommon, ill-defined, and mixed up with other things raises doubt about the utility of taking up the elaborate and, to my mind, questionable and unsupported set of hypotheses that form the major portion of the book. The theory is that Arctic hysteria results from the interlinking of environmental, physiological, psychological, and cultural factors.

The bioenvironmental mechanisms concern irregularity of light and dark periods and of the natural food resources of the Arctic. These are thought to contribute to abnormalities of calcium metabolism that in turn predispose to the periodic alteration of consciousness seen in Arctic hysteria. The psychocultural mechanisms include the Eskimo traditions, which involve models of seizure behavior on the part of shaman medicine men and the cultural use of ridicule as a means of social control, producing shame rather than guilt. It is suggested that if guilt were the characteristic response to negative sanction, one would find a high prevalence of depression. The Eskimo emphasis on shame, however, is conducive to periodic outlets in the conversion-type behavior of Arctic hysteria.

The flaws in this theory, as well as the faults in research de-

sign, measurement, and interpretation, are legion. The exposition of the theory is the intended purpose of the study and in this respect I believe the effort is largely a failure. I will mention three points.

First, the theory is so complex that it could not possibly be credited or discredited in the light of the very small sample of people found to have Arctic hysteria.

Second, some of the assumptions are neither self-evident nor evidenced in the usual sense of scientific demonstration. It is asserted, for example, that ridicule is the primary means of social control used by Eskimos. It is further asserted that the use of ridicule produces a psychological state called shame. The shame-guilt theme is popular in cross-cultural psychiatry, but I find no convincing evidence for it here or elsewhere. It would be helpful if attempts were made to clarify and measure these phenomena in different cultures and to count and compare the distributions. Until that is accomplished, the ethnographic statement that one culture is shame-ridden and another guilt-ridden seems to lead to a "standardization of error."

A third weakness of the book is the juxtaposition of highly refined, measured variables such as serum calcium levels and totally unmeasured variables such as degree of exposure to shamanism. The presumption seems to be that some indication of the influence of the latter as a model could be derived.

Probably the most important unintended value of this book is the chapter on the current use of mental hospitals among the population studied. It clearly indicates that alcoholism and depression are the most common and serious mental health problems that beset Eskimos. The hidden message is that scholars and practitioners should turn their attention to these and let the obscure hysterias be laid to rest with the publication of this volume.

Drug Abuse in Industry: Growing Corporate Dilemma, *edited by Jordan M. Scher, M.D. Springfield, Ill., Charles C Thomas, 1973, 303 pp., $11.95.*

This uneven collection of presentations is valuable principally because it illustrates the heightened interest of employers and professionals in the work adjustment of people who have problems of drug abuse. There has been a spate of monographs and papers on the subject in the past five years. *Drug Abuse in Industry* is illustrative of the genre of many recent books.

The volume is organized into seven parts. Following four introductory chapters, parts 2 and 3 focus on the impact of the drug abuser in a work setting. Part 4 is concerned with law and drug abuse, part 5 with rehabilitation, part 6 with the alcoholic, and part 7 with "special problems."

One finds a wide range of attitudes, from expressions of pride that pharmaceutical manufacturers have long had a policy not to hire any applicant with *any* record of drug abuse or suspected drug abuse to expressions of sympathetic support of vocational rehabilitation for those in treatment programs. These papers generally appear to be addressed to the employer.

It is unfortunate that many chapters reflect stereotypical and generally unscientific points of view as well as efforts to frighten the reader into taking some form of action in his company or institution. Most of the action suggested, however, is geared toward excluding the drug abuser from successful work.

The book is curiously unfocused; the chapters are not integrated into a cohesive whole. There are drum-beating statements such as "Each addict steals fifty to one hundred fifty thousand dollars worth of merchandise, equipment, or funds each year from business and industry." One may also find specific experiences of employers such as the Metropolitan Life Insurance Co., the American Telephone and Telegraph Co., and the Lockheed Aircraft Corp. that suggest otherwise. There is an excellent summary by Stephen Levy on the work experiences of heroin addicts and by Charles Winick on treatment priorities.

Although not mentioned in the book, the experience of many employers in the larger metropolitan areas is that the disruptive effect of narcotic addicts is on the wane. Since 1972, fewer and fewer new cases have come to the attention of the medical departments of work organizations. This note of optimism is nowhere seen in these pages.

ALAN A. MCLEAN, M.D.
New York, N.Y.

Uppers and Downers, *edited by David E. Smith, M.D., and Donald R. Wesson, M.D. Englewood Cliffs, N.J., Prentice-Hall, 1974, 151 pp., $2.45 (paper).*

This is a somewhat exasperating book. It is a collection of 11 papers of varying excellence and, as stated in the introductory chapter, of diverse and even conflicting views. Most of the papers were originally published in the *Journal of Psychedelic Drugs* and, at times, they are quite repetitive and redundant.

It is also difficult to guess for what readership the book is intended. Some sections are highly technical and scholarly; others are frankly political and certainly not intended exclusively for a physician audience. If it is intended for a nonprofessional readership, much of the content is too technical, e.g., the discussion of the pharmacology of amphetamines and barbiturates. However, one would have to assume from the title that it was intended for nonprofessional or paraprofessional mental health workers who deal with the problems of drug abuse. The inclusion of a glossary of drug terms strengthens this impression.

The foreword sets forth the purpose and philosophy of the book. I am in full accord with both. The heroin problem has certainly been exaggerated, the alcohol problem has been vastly underrated, and the growing and serious problems of the sedative and stimulant drugs have been largely ignored by the medical profession and the pharmaceutical industry. The writers in this book set forth their own theories as to why this is so. They argue that political and economic factors are paramount, casting little credit on the pharmaceutical establishment, the state and federal bureaucracies, the AMA, and APA. The authors are right in feeling that something ought to be done, but their proposals are somewhat simplistic and tend to be naïve.

The two editors and several of their collaborators have been active in the Haight-Ashbury Free Medical Clinic in San Francisco. They have observed at close range many of the clinical phenomena they describe so vividly in this book. One of the best chapters is on cocaine; it includes a discussion of Freud's experience with the drug. Another good article concerns the medical-legal view of amphetamines, written by John C. Kramer and Robert G. Penco. An interesting chapter is by Mike Gravel, U.S. Senator from Alaska, who mounts a rather aggressive attack on the AMA and physicians in general for their apparent indifference to what he considers the unethical action on the part of the pharmaceutical industry in promoting drugs that can be abused.

The final chapter is a typical essay by Thomas S. Szasz. He takes the position that an adult should be free to use any sort of drug or medication on himself as he sees fit. Dr. Szasz is a most

engaging debater. One ends up almost convinced that he believes what he says. This chapter is certainly out of place with the other chapters in the book, which are concerned with methods for preventing the abuse of drugs. In them we read time and again that the example of adults is one of the primary mechanisms by which the problem spreads into the juvenile population. Yet Szasz says let the adults do it but do not permit the children to do so. I, for one, must assume that he knows better than that.

This is a short book and has much in it to be commended. For the price and the time that it takes to read it, it is worthwhile. One is reminded that in an earlier time another Smith and Wesson helped "clean up the West" and bring order out of chaos. Perhaps this Smith and Wesson can help bring some order out of the present chaos of the drug problem.

GRANVILLE L. JONES, M.D.
Summit, N.J.

Life History Research in Psychopathology, vol. 2, *edited by Merrill Roff, Lee N. Robins, and Max Pollack. Minneapolis, Minn., University of Minnesota Press, 1972, 280 pp., $10.00.*

This book is an edited collection of 17 papers given at the third and fourth annual conferences of the newly formed multidisciplinary Society for Life History Research in Psychopathology. The book compiles progress reports on large-scale research programs collected into five sections pertaining to childhood, juvenile delinquency, the family, adulthood, and specific methodologies. The common threads are reliance on longitudinal study, study of congenital and environmental interactions, and careful definition of psychopathology.

The clinical populations studied cover much of the domain of psychopathology: addictions, affective disorders, alcoholism, behavioral problems in children, delinquency, psychopathic personalities, psychosomatic problems, schizophrenia, problems of the socially disadvantaged, and suicide risk are considered in research involving large numbers of subjects.

The authors of each article have clinical experience commensurate with their research sophistication. However, these clinical concerns are more fully revealed in the discussion sections appended to each chapter than in the formal papers. Many of the chapters include brief case histories to illustrate concepts; these are helpful in a book constructed around methodological advances and reports of findings.

New ways of approaching investigation and new thoughts about old concepts are presented throughout the book. Some widely held beliefs are discredited or questioned. Vaillant and McArthur question the value of the concept of "organ weakness" in psychosomatic illness. Munoz, his coworkers, and his discussants advocate dropping from usage the term "simple schizophrenia." The Dohrenwends find that cases of hardship among those accorded lower socioeconomic status are not best attributed to environmental stresses but to the personal style of "losers." Roff also focuses on class; he finds that rebellion against status deprivation is not an adequate account of delinquency among boys in the lower socioeconomic class.

A most satisfying set of papers indicates better outcomes than one might ordinarily expect for difficult populations, e.g., a paper on untreated juvenile delinquents by Roff, on narcotic addicts by O'Donnell, on alcoholics by Knupfer, and on children with a variety of behavioral problems by Chess and Thomas. This set of papers offers pleasant surprises to the stale impression that we fight a losing battle with these populations.

Methodological advances are reported throughout the book as well as in the separate section on procedures. Of particular interest is Robins' study, in which actuarial procedures were employed to estimate the causal influence—as opposed to the mere association—of one life event on another. Equally impressive are the advances made with the mental health case register described by Babigian. New assessment techniques for prediction of delinquency are described by Wirt and associates and a set of interview questions sensitive to suicide intentions is reported by Hudgens and his colleagues.

The appeal of this volume is increased by succinct historical reviews in several chapters. Garmezy's introduction discusses the various models of study used to consider etiology. He sets the stage for an appreciation of the old and new climates that make the first few years of these life history societies exciting. The reflections of Schulsinger on the history of the concept of psychopathy and those of Stott on the nature-nurture issue complement Garmezy's paper.

These authors agree that the climate from which we come is decidedly environmentalistic. Heavy emphasis is also placed on congenital influences to offset the old orientation, with the goal of a synthesis. Some of the papers offer splendid demonstrations of genetic influences, e.g., Schulsinger's study of psychopaths, which used adoptive controls, and Schuckit and associates' research on alcoholism, which used half-sibling controls. Cadoret helps tighten the case for a unipolar and bipolar distinction in depression and offers fresh evidence for a genetic explanation.

The papers in this volume are exciting references worth the time of the practitioner or researcher involved with the psychopathological populations considered here. The book can be safely recommended.

Amicus Curiae Brief in the Donaldson Case

*The amicus curiae brief of the American Psychiatric Association is published here both to emphasize a momentous historical event in psychiatry and to share with the membership the substantive thinking that went into APA participation. This brief asked the Supreme Court of the United States to rule on the right to treatment of the mentally ill and the legal responsibility of psychiatrists as to that right. The Supreme Court has agreed to accept the case; this marks the first time in the history of the United States that its highest tribunal has considered the rights of the noncriminal mentally ill. It will also be the first instance that the court will be considering the rights and duties of the psychiatrists who attend those patients. The APA brief asks the court to do justice to both patients and physicians.**

ALAN A. STONE, CHAIRMAN
APA COMMISSION ON JUDICIAL ACTION

**The preparation of this brief was complicated by the fact that in recent years APA has been reluctant to promulgate minimum doctor-patient ratios and other minimum personnel standards. One of the reasons for this reluctance has been the experience that minimal standards are all too often in legislative application converted to maximums. The brief therefore cites the last available official APA position, which has also been applied in other recent judicial determinations.

IN THE

Supreme Court of the United States

No. 74-8

J. B. O'CONNOR, M.D., *Petitioner,*

v.

KENNETH DONALDSON, *Respondent.*

Brief of American Psychiatric Association as Amicus Curiae in Support of the Grant of Certiorari

---

INTEREST OF AMICUS CURIAE

The American Psychiatric Association (A.P.A.), founded in 1844, is the nation's largest organization of qualified doctors of medicine who specialize in psychiatry. Almost 20,000 of the nation's approximately 25,000 psychiatrists are members of the Association. The A.P.A. has participated as an *amicus curiae* numerous times in cases throughout the country involving mental health issues.

Amicus believes this case to be of historic importance to the future of mental health care in the nation's public mental institutions. The landmark ruling below that there is a constitutional right to treatment, and the difficult question of how to enforce that right, are of immense concern to members of the A.P.A. and to their patients. A grant of certiorari here is essential in order to clarify presently conflicting interpretations of the rights and duties of mental patients and their psychiatrists.

CONSENT OF THE PARTIES

Amicus is filing this Brief with the consent of both parties, whose letters of consent have been filed with the Clerk.

ARGUMENT

The opinion below decides two questions that are fundamental to the future course of mental health care in this country. First, does the involuntarily committed patient at a state mental institution have a constitutional right to a level of treatment reasonably calculated to improve his or her mental condition? Second, assuming there is such a right, who should be responsible for providing the remedy when an institution has inadequate resources to provide that level of treatment?

The court below answered the first question by holding that there *is* a constitutional right to an adequate level of treatment, and that Respondent Kenneth Donaldson did not receive this minimum level of care. Amicus A.P.A. wholeheartedly supports the Court of Appeals decision on this issue. Indeed, as we will discuss in Part I, below, Amicus believes that the importance of this principle and the conflicts between the states as to its enforcement require a grant of certiorari here. An affirmance of the decision below on this point could provide invaluable guidance to the lower courts and to responsible state agencies by clarifying the contours of this new right to treatment.

Regarding the second major question—the proper remedy for violation of this new right—Amicus believes the court below committed a serious error. As we will discuss in Part II, below, the Court of Appeals has held that the psychiatrist who chooses to work for a woefully understaffed state mental institution can be held *personally* liable when a patient receives insufficient treatment, even though the institution has such inadequate resources that it would be impossible for its doctors to provide adequate care to all their patients. This ruling conflicts with numerous decisions from other courts holding that state officials are not liable personally for damages when in good faith they have been unable to comply with a newly declared constitutional right. Moreover, holding the doctor rather than the institution liable for damages will almost certainly deter psychiatrists from working at the institutions where they are most needed—those where the current level of treatment is the most inadequate. This Court should grant certiorari so that this ruling does not negate much of the potential for good inherent in the lower court's holding on the right-to-treatment issue.

I. THIS COURT SHOULD GRANT CERTIORARI HERE TO AFFIRM THE CONSTITUTIONAL RIGHT TO TREATMENT.

The present case starkly reveals the overwhelming shame and challenge of this nation's mental health care system. The deplorable conditions shown to exist at Florida State Hospital at Chattahoochee ("Chattahoochee") are all too common in many jurisdictions throughout the country. Legislatures and officials in numerous states routinely deny mental hospitals the resources needed to treat their involuntarily committed residents like patients, rather than like prisoners. This Court should grant certiorari so that all such institutions (and the legislatures that support them) will understand their legal duties and begin providing at least the basic minimum level of care that the Fifth Circuit has recognized is a constitutional requirement.

During Mr. Donaldson's fourteen-year confinement, the ratio of patients per staff psychiatrist ranged from 560-1 all the way up to 1000-1. Petition for Certiorari, at 6. After performing other medical and administrative duties, the average hospital staff psychiatrist is able to devote only 47% of his or her time to direct patient care.[1] Thus, if each doctor spent an equal amount of time with each patient, as little as one or two minutes per week would have been available for psychiatric "treatment" of each patient at Chattahoochee. Meaningful psychiatric care was not, and cannot be, provided under such circumstances.

[1] JOINT INFORMATION SERVICE, AMERICAN PSYCHIATRIC ASS'N & NAT'L ASS'N FOR MENTAL HEALTH, ELEVEN INDICES 14 (1971).

The American Psychiatric Association has promulgated standards for the minimum level of staffing necessary for a public mental hospital to provide even the lowest level of acceptable care.[2] These are truly *minimun* standards, since they "represent a compromise between what was thought to be adequate and what it was thought had some possibility of being realized." Solomon, *The American Psychiatric Association in Relation to American Psychiatry*, 115 AM. J. PSYCHIAT. 1, 7 (1958). Yet even these minimal standards, which have been accepted as guideposts by the courts, *see Rouse* v. *Cameron*, 373 F.2d 451, 457-58 & n.33 (D.C. Cir. 1966); *see also Wyatt* v. *Stickney*, 344 F. Supp. 373, 383 (M.D. Ala. 1972), *appeal docketed sub nom. Wyatt* v. *Aderholt*, No. 72-2634 (5th Cir., Aug. 1, 1972), demonstrate that Chattahoochee needed a vastly larger number of doctors than it actually had in order to provide adequate treatment to its resident population. The A.P.A. standards allow no more than thirty acutely ill patients, or 150 chronically ill patients, per full-time psychiatrist. Thus, while each psychiatrist at Chattahoochee averaged 750 patients, of whom 350 were acutely ill,[3] minimum staffing standards demanded *sixteen* full-time psychiatrists in order to treat those patients.

The necessity for a grant of certiorari here to affirm mental patients' constitutional right to treatment arises from the fact that state mental hospital overcrowding and understaffing are common today far beyond the confines of Chattahoochee or the Fifth Circuit. "In many of our hospitals about the best that can be done is to give a physical examination and make a mental note on each patient once a year, and often there is not even enough staff to do this much." Solomon, *The American Psychiatric Association in Relation to American Psychiatry*, 115 AM. J. PSYCHIAT. 1, 7 (1958). A comprehensive report in the early 1960's suggested that no public mental hospital in the United States met minimum staffing requirements. U. S. SURGEON GENERAL'S AD HOC COMM. ON PLANNING FOR MENTAL HEALTH FACILITIES, PLANNING OF FACILITIES FOR MENTAL HEALTH SERVICES 39 (1961). Although there has been considerable improvement in recent years,[4] current studies continue to reveal many large mental hospitals with patient-doctor ratios of 500-1 and even higher.[5]

When institutional resources are so low, hospitals become indistinguishable from prisons. Patient "care" is little more than custody, and the treatment rationale for involuntary commitment becomes a cruel hoax. Like Kenneth Donaldson, there are many thousands of people throughout the country who, although suffering from serious mental illness, have committed no crimes and shown no obvious signs of dangerousness to others, *see* 493 F.2d at 517, but whom society has forced into mental institutions to receive treatment for their own good. This *"parens patriae"* rationale rings hollow, indeed, when "treatment" turns into neglect.

The court below was the first federal court of appeals to rule that involuntarily committed mental patients have a constitutional right to treatment. *See* 493 F.2d at 519 & n.9. A few courts have rejected the existence of such a right. *See, e.g., People ex rel. Anonymous* v. *La Burt*, 14 App. Div. 2d 560, 218 N.Y.S. 2d 738 (1961), *appeal dismissed and cert. denied*, 369 U.S. 428 (1962). More commonly, however, state officials simply assume that no such right exists when they make their staffing and resource decisions, and mental patients fail to bring any judicial action to challenge those decisions. This Court has already noted how infrequently mental patients litigate the states' powers in this area. *Jackson* v. *Indiana*, 406 U.S. 715, 737 (1972). Thus, because of the condition of the people whose rights are affected, conflicts between different states' policies and constitutional interpretations regarding the right to treatment do not necessarily result in a conflict between circuit court decisions. Nevertheless, the conflict is very real and very crucial to the citizens in many jurisdictions outside the Fifth Circuit who are being confined without constitutionally adequate treatment.

This Court should grant certiorari to resolve those conflicting state practices by affirming that there is a constitutional right to treatment.

[2] AMERICAN PSYCHIATRIC ASSOCIATION, STANDARDS FOR HOSPITALS AND CLINICS 61 (rev. ed. 1958).

[3] These figures are roughly the midpoints of the data range during the fourteen-year period for each category. *See* Petition for Certiorari, at 6-7.

[4] *See* NAT'L INST. MENTAL HEALTH, STAFFING OF MENTAL HEALTH FACILITIES, UNITED STATES, 1972, at 7-9 (DHEW Pub. No. ADM 74-28, 1974).

[5] While the nationwide average patient-psychiatrist ratio in state mental hospitals is now down to approximately 70-1, *county* mental hospitals still average 500 patients per psychiatrist. *Id.* at 53. The range between the highest and lowest statewide patient-psychiatrist ratio (counting all of each state's public mental hospitals) is a staggering 14,300%, the worst state having 143 times more patients per doctor than the best state. *Compare* NAT'L INST. MENTAL HEALTH, STATISTICAL NOTE 109, STAFFING OF STATE AND COUNTY HOSPITALS, UNITED STATES, 1973, at Table 1 (Aug., 1974) (Alabama), *with id.* at Table 1 (Colorado). Reports of individual mental hospitals with a thousand or more patients per psychiatrist are "well known." *Hearings on the Constitutional Rights of the Mentally Ill Before the Subcomm. on Constitutional Rights of the Senate Comm. on the Judic.*, 91st Cong., 1st & 2d Sess. 30, 51 (1969-70).

II. THE LOWER COURT'S STANDARD FOR PERSONAL LIABILITY CONFLICTS WITH THE PRINCIPLE OF PIERSON v. RAY AND WILL HAMPER ENFORCEMENT OF PATIENTS' RIGHT TO TREATMENT.

After concluding that there is a constitutional right to treatment, the Court of Appeals faced the equally important issue of determining the appropriate remedy for violation of that right. On this issue Amicus believes the lower court seriously erred. The record shows that at Chattahoochee there were so few doctors that it was impossible for them to provide adequate treatment to all their patients. *See* pp. 4-5, *supra*. Yet, the court held that those doctors who stay at the institution and try to treat the huge number of patients there can be liable *personally* for any damages the patients suffer from lack of treatment. This ruling is fundamentally unfair to the doctors and is contrary to the patients' interest in obtaining more medical treatment.

At least prior to this case, the law was well settled that a state official should not be held personally liable for a civil rights violation when he or she had tried in good faith to follow then-existing constitutional principles, even if those principles later were overturned. As this Court held in *Pierson* v. *Ray*, 386 U.S. 547, 557 (1967), state officers are not "charged with predicting the future course of constitutional law." They "neither can nor should be expected to be seers in the crystal ball of constitutional doctrine." *Westberry* v. *Fisher*, 309 F. Supp. 12, 17 (D. Me. 1970).

In the instant case, a constitutional right to treatment was little more than a gleam in the eye of its most ardent proponent during Mr. Donaldson's confinement, which began in 1957. The article generally credited as the first even to suggest such a right appeared in 1960. Birnbaum, *The Right to Treatment*, 46 A.B.A.J. 499 (1960); *see* 493 F.2d at 519-520 & nn.12, 14. Several courts during the 1960's refused to recognize the existence of a constitutional right to treatment. *See, e.g., People ex rel. Anonymous* v. *La Burt*, 14 App. Div. 2d 560, 218 N.Y.S.2d 728 (1961), *appeal dismissed and cert. denied*, 369 U.S. 428 (1962). Indeed, Mr. Donaldson himself brought several earlier right-to-treatment claims against Dr. O'Connor, and the courts consistently rejected these claims. *See, e.g., Donaldson* v. *O'Connor*, 234 So. 2d 114 (Fla. 1969), *cert. denied*, 400 U.S. 869 (1970). *See also Donaldson* v. *O'Connor*, 390 U.S. 971 (1968); *Donaldson* v. *Florida*, 371 U.S. 806 (1962); *In re Donaldson*, 364 U.S. 808 (1960). It was not until 1971, the year of Mr. Donaldson's release from Chattahoochee, that the first court held that there should be a constitutional right to treatment. *Wyatt* v. *Stickney*, 325 F.Supp. 781 (M.D. Ala. 1971), *appeal docketed sub nom. Wyatt* v. *Aderholt*, No. 72-2634 (5th Cir., Aug. 1, 1972).

Under these circumstances it is unfair and contrary to the principle this Court stated in *Pierson* v. *Ray* to apply the right-to-treatment principle retroactively by holding Dr. O'Connor personally liable for damages. Other Circuits have recognized the necessity of "providing conscientious state officials with some protection against the cutting edge of a rapidly developing legal doctrine." *Eslinger* v. *Thomas*, 476 F.2d 225, 229 (4th Cir. 1973). In *Eslinger*, plaintiff challenged the policy of the clerk of the South Carolina State Senate that women were ineligible to serve as senate pages. The Fourth Circuit held that injunctive relief was proper, since the discriminatory policy ran afoul of current constitutional requirements of equal protection. The court went on, however, to reverse the lower court's ruling that the clerk should be liable for damages. The court noted that the defendant's actions had taken place at a time when the law generally tolerated sex-based classifications. *Id.* at 230 & n.5. "Although the clerk may have acted with little sensitivity . . . he acted in the light of a long-standing, albeit vaguely defined, 'custom' . . . . He did no more, or less, than what had always been done." *Id.* at 229. The Fourth Circuit concluded that the defendant should not be liable for failing to foresee a new constitutional principle. *Id.; accord, e.g., Skinner* v. *Spellman*, 480 F.2d 539 (4th Cir. 1973) (no damages against official acting in "reasonable good faith reliance on what was standard operating procedure"); *Clarke* v. *Cady*, 358 F. Supp. 1156, 1163 (W.D. Wisc. 1973) (prison warden "immune from damages under § 1983 when he reasonably relies upon the validity of a prison practice which has only subsequently been determined to be unconstitutional"); *Collins* v. *Schoonfield*, 363 F. Supp. 1152, 1156 (D. Md. 1973) ("it would contravene basic notions of fundamental fairness if prison officials were held to be liable monetarily for acts which they could not reasonably have known were unlawful").

In the instant case, even if Dr. O'Connor had possessed the prescience to recognize Mr. Donaldson's constitutional right to adequate treatment, Amicus fails to see how Dr. O'Connor could have responded in a way that would have satisfied the court below. Petitioner had as many as *sixteen times* more patients than it was possible to treat properly under accepted professional standards. *See* pp. 4-5, *supra*. Moreover, Mr. Donaldson himself rejected for religious reasons [6] the medication therapy which is generally recognized as one of the most effective

[6] *See Winters* v. *Miller*, 446 F.2d 65 (2d Cir.), *cert. denied*, 404 U.S. 985 (1971) (involuntarily committed Christian Scientist has right to refuse medication treatment). *See also Developments in the Law—Civil Commitment of the Mentally Ill*, 87 HARV. L. REV. 1190, 1350 (1974).

forms of treatment for his condition.[7] Thus, the staff time and resources needed for adequate treatment of Mr. Donaldson simply were not available at Chattahoochee.

It is no answer to say, as did the Court of Appeals, that Dr. O'Connor should be personally liable because he did not devote as much time to Mr. Donaldson as did Dr. Hanenson, another one of Mr. Donaldson's attending physicians. *See* 493 F.2d at 518.[8] When only one or two minutes per week is available to "treat" each patient, see p. 4, *supra*, a doctor must either devote insufficient time to all patients, or give extra time to some at the expense of many others. The record shows that Dr. Hanenson decided to give a disproportionately large amount of his time to Mr. Donaldson—more time than any doctor at Chattahoochee possibly could devote to each of the 560-1000 persons for whom he or she was responsible. Under the Court of Appeals ruling, however, the extra attention a doctor gives to one patient can become the standard which every doctor in that institution must meet for every patient. Inevitably, to comply with such a rule doctors must provide identical amounts of time to each patient, regardless of levels of need. This "lowest common denominator" approach substitutes a mathematical rule for medical judgment. It ignores the harsh reality that even the sharpest knife cannot cut a small pie into enough servings to sustain 1000 starving people. The fact is that no matter how each doctor at Chattahoochee chose to divide it, his total time for patient care was just too small to go around.

It is an unspeakable tragedy when a mentally ill person is crowded into a facility like Chattahoochee, given little or no medical treatment, and allowed to remain there for years on end. Amicus believes strongly that such conditions violate the patient's constitutional right to treatment. The responsibility for a remedy, however, must lie with those who have the power to correct these conditions.[9]

The courts can find effective remedies for these problems by focusing on the institutional setting and resources available for treatment. In *Wyatt* v. *Stickney*, 325 F. Supp. 781 (M.D. Ala. 1971), *on submission of proposed standards*, 334 F. Supp. 1341, *enforced*, 344 F. Supp. 373, *appeal docketed sub nom. Wyatt* v. *Aderholt*, No. 72-2634 (5th Cir., Aug. 1, 1972), the court has used its equitable power to require state institutions to increase their staff-patient ratio to the level necessary to provide adequate care. *See* 344 F. Supp. at 387. The American Psychiatric Association is participating in the *Wyatt* case, supporting the right to treatment and urging the court to order a variety of needed institutional reforms. *See* Motion of American Psychiatric Association for Leave to Participate as *Amicus Curiae*, *Wyatt* v. *Aderholt*, No. 72-2634 (5th Cir., filed Dec. 4, 1972). The other right-to-treatment cases relied upon by the court below similarly focus on institutional reforms and injunctive relief. *See Welsch* v. *Likins*, 373 F. Supp. 487 (D. Minn. 1974); *Stachulak* v. *Coughlin*, 364 F. Supp. 686 (N.D. Ill. 1973). *See also Rouse* v. *Cameron*, 373 F.2d 451, 458-59 (D.C. Cir. 1966) (institution must release patient receiving inadequate treatment). When a state institution fails to meet these minimum standards identified by the courts, a damage action should lie *against the responsible state agency*.[10] *See Whitree* v. *State*, 56 Misc. 2d 693, 290 N.Y.S. 2d 486 (Ct. Cl. 1968) ($300,000 award against state for improper custodial confinement of mental patient). Indeed, such actions may be the most effective method to loosen the legislatures' pursestrings, so that sufficient resources do become available. *See* 82 HARV. L. REV. 1771, 1776-77 (1969).

Instead of such institutional remedies, the Fifth Circuit has held that the doctor who works on the staff of an overcrowded hospital is personally liable for damages to patients he or she is unable to treat. This decision has frightening implications for the very patients whose right to treatment the court was seeking to protect. Unless this Court grants certiorari it would be foolish for qualified doctors to continue working at Chattahoochee or the many other institutions that are similarly understaffed. Rather than stay in a system where their best efforts could not eliminate constant exposure to large damage awards, doctors will seek positions in private practice, or at the better-staffed institutions. Rather than increasing

[7] *See, e.g.*, Hollister, *Choice of Antipsychotic Drugs*, 127 AM. J. PSYCHIAT. 186, 188 (1970); VETERANS ADMINISTRATION, ANTIPSYCHOTIC, ANTIANXIETY & ANTIDEPRESSANT DRUGS 3 (MB-11, Sept. 15, 1966).

[8] Although the lower court paid lip service to the propriety of allowing doctors a "good faith" defense in cases of this kind, *see* 493 F.2d at 527, it effectively eliminated such a defense by ignoring the evidence that insufficient resources at Chattahoochee made adequate treatment impossible. *See* pp. 4-5, *supra*.

[9] Supporters of the right to treatment generally recognize that the understaffing and lack of physical facilities that plague our state mental institutions are not the fault of the psychiatrists or others who work there. "Our society should be grateful to, rather than adversely critical of, the personnel who continue to work in these institutions under the present trying conditions." Birnbaum, *The Right to Treatment*, 46 A.B.A.J. 499, 500 (1960); *accord, e.g.*, Birnbaum, *Some Remarks on the Right to Treatment*, 23 ALA. L. REV. 623, 628 (1971).

[10] The doctor should be personally liable, of course, if he commits any acts of malpractice. *See generally* Morse, *Tort Liability of the Psychiatrist*, 18 SYR. L. REV. 691 (1967).

the quality and quantity of treatment available at Chattahoochee, the decision below will lead to just the opposite result.

The Court of Appeals indicated in its opinion that the "core of the charge" against Dr. O'Connor was that he confined Mr. Donaldson "knowing that [he] was not receiving adequate treatment and knowing that absent such treatment the period of his hospitalization would be prolonged." 493 F.2d at 513. The tragic truth is that the grossly inadequate resources in our state mental hospitals today require many of our country's best psychiatrists in painful candor to confess their guilt to this same charge. The question this Court should review is whether our judicial system can help correct the institutional inadequacies that are depriving thousands of mental patients of their fundamental rights, or whether instead the judicial response will be to punish and drive away the people who are doing the most to deal with these problems.

CONCLUSION

For the foregoing reasons, Amicus respectfully urges this Court to grant a writ of certiorari.

Respectfully submitted,

CHARLES C THOMAS • PUBLISHER

THE MALPRACTICE OF PSYCHIATRISTS: Malpractice in Psychoanalysis, Psychotherapy and Psychiatry *by* **Donald J. Dawidoff,** *Practicing Attorney, New York.* The author describes possible areas of malpractice by psychiatrists and examines both the nature of and remedy for malpractice in the verbal therapies of psychoanalysis and psychotherapy. The difficulties awaiting application of the canons of malpractice to such therapy are explored at length. Also. canons of malpractice to such therapy are explored at length. Also, the specialized legal theories of breach of fiduciary duty, undue influence and words negligently spoken are applied to psychotherapy and psychoanalysis. A sampling of psychiatric literature is set forth to indicate the doctrinal recognition of concepts described. *'73, 184 pp., $9.75*

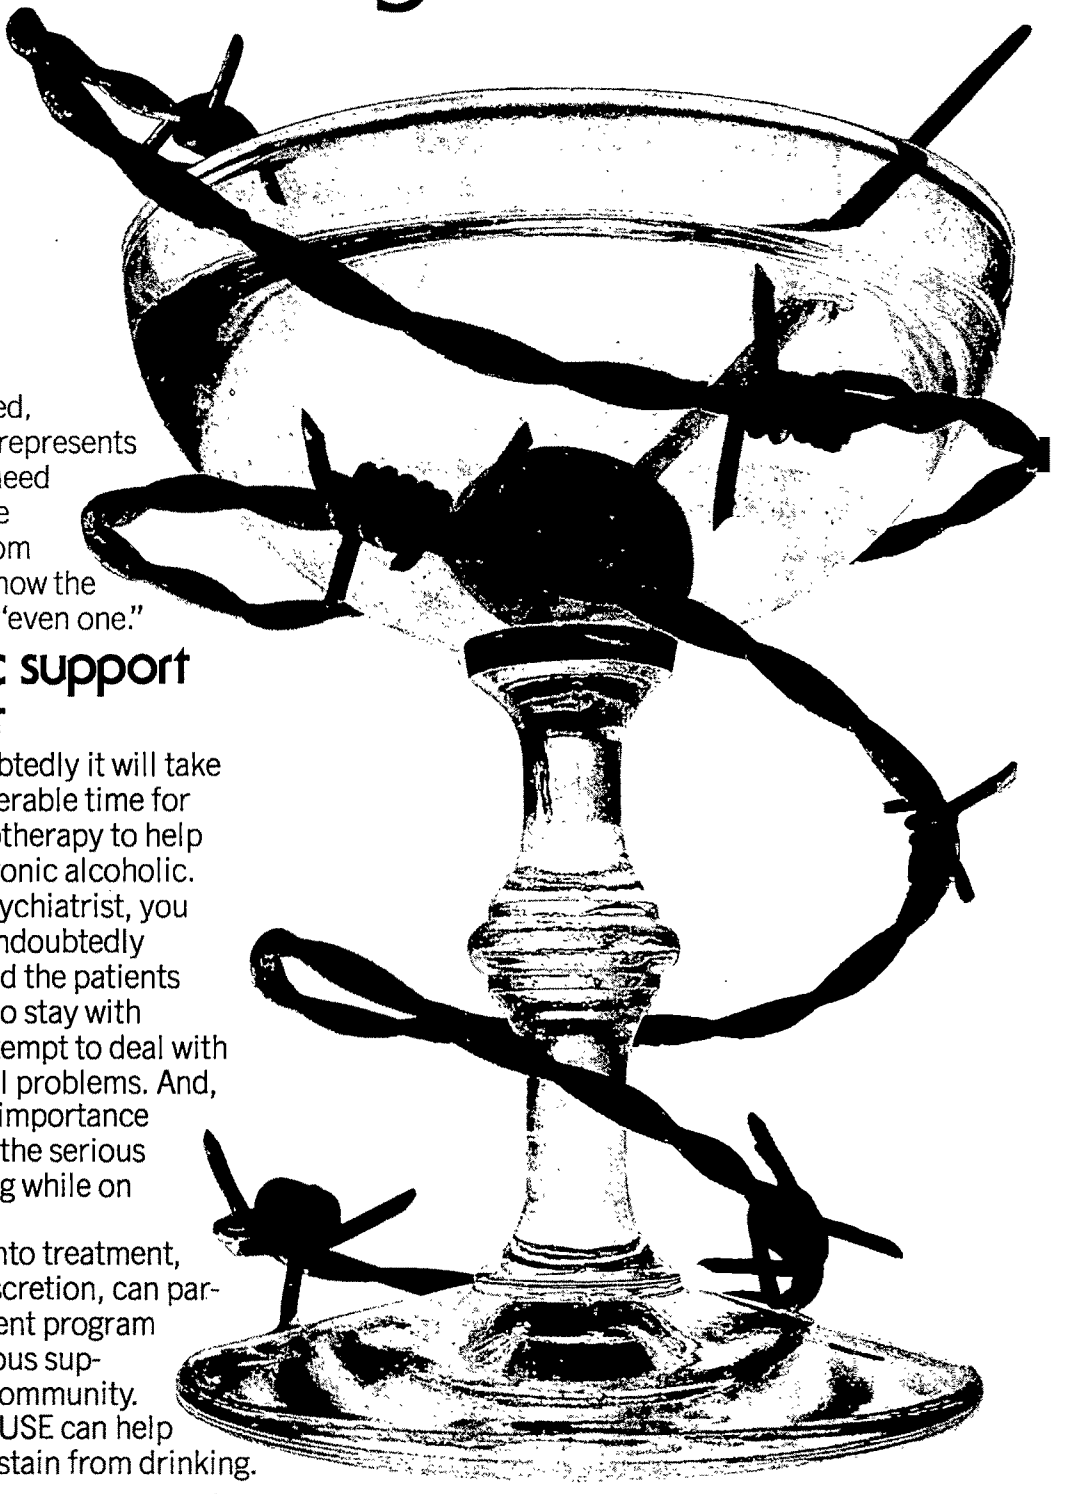
EPIDEMIOLOGICAL PSYCHIATRY *by* **Brian Cooper,** *Univ. of London, London, England, and* **H. G. Morgan,** *Univ. of Bristol, Bristol, England. Foreword by* **Michael Shepherd.** Written primarily for psychiatrists in training or in clinical practice, this book demonstrates that the improved perspective gained through the epidemiological approach can answer many questions regarding the nature and treatment of mental illness. A review of the principal ways in which epidemiological research has contributed to current knowledge of the distribution, natural history and causes of psychiatric morbidity is presented. Possible future developments are assessed, particularly in relation to the impact on epidemiology of new clinical laboratory and statistical research techniques. *'73, 232 pp., 13 il., 40 tables, $12.50*

A PRACTICAL HANDBOOK OF PSYCHIATRY *edited by* **Joseph R. Novello,** *University of Michigan, Ann Arbor, Michigan. (17 Contributors)* Part I of this handy text provides an immediate source of sound, practical information for use on the "firing line" of everyday work by psychiatrists, other medical practitioners and medical students. Part II presents reading lists, available psychiatric journals and training opportunities in some of the subspecialties. A final section is a concise compilation of addresses of professional organizations and institutions related to psychiatry. This is a handbook containing a maximum of clinically useful information with a minimum of verbiage in a brisk and readable format. *'74, 648 pp., 10 il., 47 tables, $16.75*

INDECENT EXPOSURE *by* **John M. Macdonald,** *Univ. of Colorado, Denver. Chapter by* **N. K. Rickles.** This book is based not only upon a study of offenders and their victims, but also upon analysis of the Denver Police Department records on 200 consecutive reports of indecent exposure. Psychological aspects of exhibitionism receive particular attention and one chapter considers the mothers of exhibitionists and their role in promoting this unusual behavior. Police raids on nudist camps, criminal investigation of indecent exposure, legal aspects of this problem, sexual psychopath laws and the punishment of offenders are reviewed. A concluding chapter on treatment includes recent advances in behavior therapy. *'73, 180 pp., 10 tables, $7.95*

A PSYCHIATRIC STUDY OF MYTHS AND FAIRY TALES: Their Origin, Meaning and Usefulness. An Enlarged and Thoroughly Revised Second Edition of A Psychiatric Study of Fairy Tales (2nd Ed.) *by* **Julius E. Heuscher,** *Stanford Univ., Stanford, California.* The images of myths and fairy tales remain familiar to the child within us, to the artist within our soul. Thus they may, even today, help the adult's quest for harmony and wholeness that is threatened by onesidely intellectual and sensory orientations. These images may also be introduced beneficially in psychotherapy. The adult who develops a fine awareness for their potential depth and power can communicate to the child the content of this lost and yet always young language. *'73, 448 pp., 11 il., 14.95*

LIFE STRESS AND ILLNESS *edited by* **E. K. Eric Gunderson,** *Univ. of California, San Diego, and* **Richard Rahe,** *Univ of California, Los Angeles. (19 Contributors)* This book is based upon contributions to the NATO-sponsored Symposium on "Life Stress and Illness" held in Beito, Norway. It critically examines relationships between stressful life events and various types of illness. A major emphasis in the book is the development of quantitative techniques for the measurement of life stress and the scaling of specific life events which have special significance for the onset of disease. The physiological and psychological effects of severe stress, such as prison confinement, are described as well as the effects of milder everyday stress. *'74, 276 pp., 25 il., 27 tables, $19.50*



OCCUPATIONAL STRESS *edited by* **Alan McLean,** *New York Hospital, White Plains.* This book is the first to present widely held concepts of occupational stress in a single volume. The purpose of the Occupational Mental Health Conference at the Center for Occupational Mental Health was to bring together representatives from the many concerned disciplines to present their viewpoints so that a picture of current thinking could be obtained and the various definitions of the term understood. Based upon this conference, this book presents theoretical concepts, research results and various specific suggestions for coping with stress-related problems. Psychiatric, psychoanalytic and psychophysiological considerations are discussed as stemming from role theory. *'74, 128 pp., 21 il., 9 tables, $9.75*

A NEUROPHYSIOLOGICAL MODEL OF EMOTIONAL AND INTENTIONAL BEHAVIOR *by* **John L. Weil,** *Harvard Medical School, Boston.* Researchers, theoreticians and clinicians will be interested in the presentation of this model of behavior constructed in answer to the current need for establishing lines of communication between the fields of neurophysiology, experimental psychology and clinical psychiatry. The clarity of the colored illustrations, diagrams, flow charts and tables will be welcomed by students in medicine and physiological psychology as well as by the reader who is seeking to understand central nervous system processes pertaining to the interaction of emotion, cognition and intention. *'74, 204 pp. (7 x 10), 50 il. (24 in full color), 28 tables, $15.75*

ANTABUSE: "Social security" for the alcoholic who wants to stop drinking...

The temptation is resisted, ANTABUSE (disulfiram) represents the security alcoholics need in any situation. They are better able to abstain from drinking because they know the consequences of taking "even one."

until psychiatric support can do the rest

Undoubtedly it will take considerable time for psychotherapy to help the chronic alcoholic. As a psychiatrist, you have undoubtedly selected the patients who are best motivated to stay with ANTABUSE while you attempt to deal with the underlying emotional problems. And, of course, you know the importance of reminding patients of the serious consequences of drinking while on ANTABUSE.

Once sober, and well into treatment, the alcoholic, at your discretion, can participate in a total treatment program which makes use of various supportive resources in the community. In the meantime, ANTABUSE can help the chronic alcoholic abstain from drinking.

BRIEF SUMMARY
(For full prescribing information, see package circular.)

ANTABUSE® (disulfiram) in Alcoholism

INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)

CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, e.g. cough syrups, tonics, and the like, should not be given ANTABUSE.

ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.

The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.

THE ANTABUSE-ALCOHOL REACTION: ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.

The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.

DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.

Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.

It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.

Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.

CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.

USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE (disulfiram) should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.

PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)

Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.

Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)

Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.

In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.

Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.

There have been reports of polyneuritis and peripheral neuritis, and rare instances of optic neuritis. One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.

DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.

INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.

MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.

NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE (disulfiram), report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.

DURATION OF THERAPY: The daily, uninterrupte administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even year

TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.

However, where a test reaction is deemed necessary, the suggested procedure is as follows:

After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (½ oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.

MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.

HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100. No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000.

ANTABUSE®

BRAND OF DISULFIRAM

In the treatment of clinically significant depression...

Now added dosage versatility...

- **An important alternative in fitting the medication to the patient's needs**

  Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. Of course, ELAVIL may be administered two, three, or four times as well as once a day. This dosage versatility allows prescribing precisely for the patient's needs.

- **Once-a-day dosage schedule for adult outpatients**

  Therapy should be initiated with 50 mg to 100 mg at bedtime. This may be increased by 25 or 50 mg added to the bedtime dose as necessary to a maximum daily dose of 150 mg. The usual maintenance dose is 50 to 100 mg a day given at bedtime, though in some patients, 40 mg per day is sufficient.

- **Greater patient compliance**

  The simplicity of once-a-day dosage at bedtime makes it easier for patients to adhere to a regimen—an especially important consideration in depressed patients whose self-motivation may be at a low ebb.

Should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

once a day at bedtime

Please see addendum on following page for other details of dosage and administration including divided daily doses, dosage in hospitalized patients, and dosage in elderly and adolescent patients.

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

added dosage versatility in clinically significant depression

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of tricyclic antidepressant poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

addendum

MSD MERCK SHARP & DOHME

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for initial therapy in adult outpatients. Starting dosage is usually 75 mg daily in divided doses or 50 to 100 mg once a day at bedtime. If necessary, this dosage may be increased gradually to a total of 150 mg a day. When doses are divided, dosage increases are made preferably in the late afternoon or at bedtime. A sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

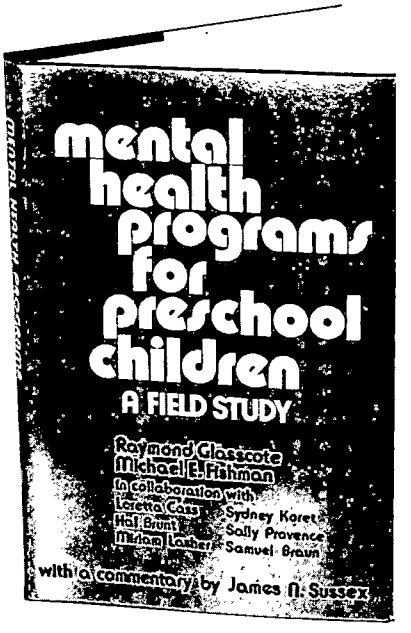
50 mg (beige)

The 50-mg tablet may be advantageous whenever higher dosages are required, or when the single daily dose is given at bedtime. The 50-mg tablet may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

INJECTION
10 mg per ml



For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

May be the start of a better life for the epileptic

About nine out of ten epileptics suffer their first seizure in childhood.[1] Certain physical and psychic postseizure evidence—a badly bitten tongue, broken or dropped objects, amnesia, exhaustion—may suggest grand mal. Once the diagnosis of epilepsy has been established, *MYSOLINE (primidone) may mean the start of a seizure-free life.*

Early therapy for control of grand mal, focal and psychomotor epilepsy. Used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. Based c years of clinical success, MYSOLINE has earn the reputation of being an *excellent* drug for cc trol of grand mal epilepsy.[2-4] But its usefulness not confined to this type alone: MYSOLINE h proved to be valuable for control of psychomotor and focal epilepsy[5] as well.

Improves response to concomitar therapy. When other anticonvulsants prove be inadequate, adding MYSOLINE to the regim can improve seizure control in grand mal and p

:homotor epilepsy. A double-blind comparative study[6] shows that the combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.

Effective changeover therapy. Unsatisfactory performance or important side effects may force discontinuation of the patient's existing anticonvulsant therapy. For more effective control, MYSOLINE may be added to the patient's present regimen, then gradually substituted for the original medication. The changeover to MYSOLINE is frequently warranted when grand mal is refractory to phenobarbital, with or without diphenylhydantoin.[7]

Mysoline® (primidone)
May be the start of a better life for the epileptic

initial and maintenance therapy for grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY

(For full prescribing information, see package circular.)

MYSOLINE® Brand of **PRIMIDONE**

Anticonvulsant

INDICATIONS: MYSOLINE, either alone or in combination, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

Use in pregnancy: The effect of primidone on the human fetus has not been studied, and the benefit of administration of any drug during pregnancy must be weighed against any possible effect on the fetus.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking MYSOLINE and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

In nursing mothers: There is evidence that in mothers treated with MYSOLINE, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. On rare occasion, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE (primidone) and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 mg. Increments of 250 mg. are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 Gm. A typical dosage schedule for the introduction of MYSOLINE is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg., with gradual weekly increases of 125 mg. a day, to a daily total usually between 500 mg. and 750 mg.

In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances: for initiation of combination therapy; during "transfer" therapy; for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.).

HOW SUPPLIED: MYSOLINE *Tablets*—No. 430—Each tablet contains 250 mg. of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg. of primidone (scored), in bottles of 100 and 500. MYSOLINE *Suspension*—No. 3850—Each 5 cc. (teaspoonful) contains 250 mg. of primidone, in bottles of 8 fluidounces.

A shot against cancer?

One day the scariest thing about cancer may be the needle that makes you immune to it.

The theory: build up the body's defense to fight off a disease naturally.

Dramatic research in this direction is going on right now.

Scientists are working on mechanisms to make the body reject cancer.

And the promise for the future is staggering.

Wouldn't you feel good knowing you contributed to the research?

Feel good.

Please contribute. Your dollars will help further *all* our cancer research.

We want to wipe out cancer in your lifetime.

Akineton® hydrochloride (biperiden hydrochloride) Tablets/Ampules

Contraindications: The only known contraindication is sensitivity to Akineton hydrochloride.

Warnings: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients.

Precautions: Caution should be observed in patients with manifest glaucoma, though no prohibitive rise in intraocular pressure has been noted following either oral or parenteral administration. Patients with prostatism or cardiac arrhythmia should be given this drug with caution. Occasionally, drowsiness may occur.

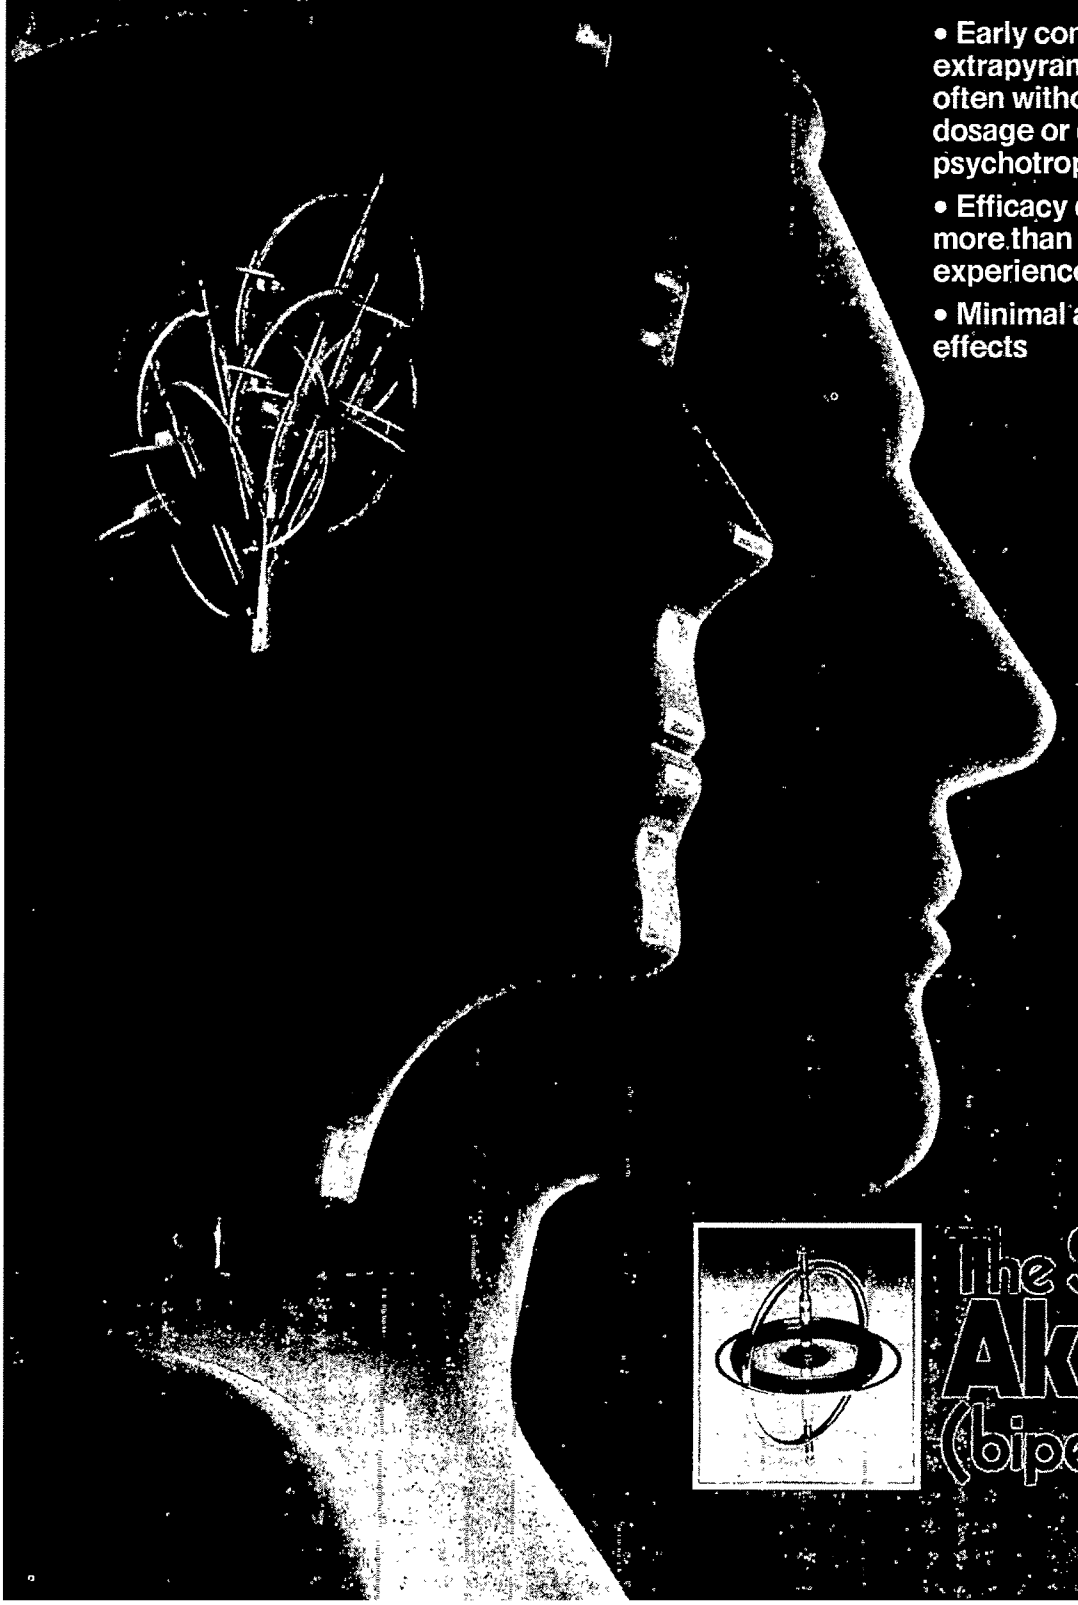
Adverse reactions: Adverse reactions encountered are primarily dry mouth and blurred vision. These side effects are usually slight and can be overcome by judicious reduction of dosage. If gastric irritation occurs, it can be avoided by administering during or after meals.

Dosage and Administration: Doses required to achieve therapeutic goal are variable and must be individually and gradually adjusted.

Parkinson's disease: 1 tablet, 2 mg. three or four times daily.

Drug-induced extrapyramidal disorders: 1 tablet, 2 mg. one to three times daily.

How Supplied:



Akineton hydrochloride tablets, 2 mg. each, bisected—bottles of 100 and 1000.

Akineton lactate ampules, 1 ml. each containing 5 mg./ml. in an aqueous 1.4 percent sodium lactate solution. No added preservative. Boxes of 10.

Additional literature available upon request.

Knoll Pharmaceutical Company
Whippany, New Jersey 07981

STABILIZE
EXTRAPYRAMIDAL REACTIONS

- Early control of drug-induced extrapyramidal reactions often without reduction in dosage or discontinuance of the psychotropic agent
- Efficacy demonstrated in more than a decade of clinical experience
- Minimal anticholinergic side effects

The Stabilizer
Akineton®
(biperiden)

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized, and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In clinically significant depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD)

helps establish early therapeutic rapport

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. May enhance response to alcohol and effects of barbiturates and other CNS depressants. Possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent administration with electroshock therapy may increase hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue drug several days before elective surgery, if possible. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of other tricyclic antidepressant poisoning.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

MSD 26 5 mg (orange)

MSD 47 10 mg (yellow)

The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.

In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.

When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.

(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

May enhance other remedial efforts in treating MBD[1]

ONLY WHEN MEDICATION IS INDICATED

Ritalin®
(methylphenidate)

Ritalin...of proven value when used as part of a complete therapeutic and remedial MBD program

More than a decade of clinical experience shows that Ritalin helps improve ratings of behavior, attentiveness, performance IQ, motor control, and speech productivity in children with Minimal Brain Dysfunction (MBD).[1-5]

Currently a drug of choice in many MBD situations,[6] Ritalin can play an important part in the total rehabilitation program of the MBD child. And proper management is essential to the overall (educational, social, and emotional) development of the child's potential.

Dosage should be periodically interrupted in the presence of improved motor coordination and behavior. Often, these interruptions reveal that the child's behavior shows some "stabilization" even without chemotherapy, permitting a reduction in dosage and eventual discontinuance of drug therapy.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)
TABLETS

INDICATION
Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)
Special Diagnostic Considerations
Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.
Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.
Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.
CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.
WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.
Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.
Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC, differential, and platelet counts are advised during prolonged therapy.
ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.
In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.
DOSAGE AND ADMINISTRATION
Children with Minimal Brain Dysfunction (6 years and over)
Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.
If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.
Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.
Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.
HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak blister units of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

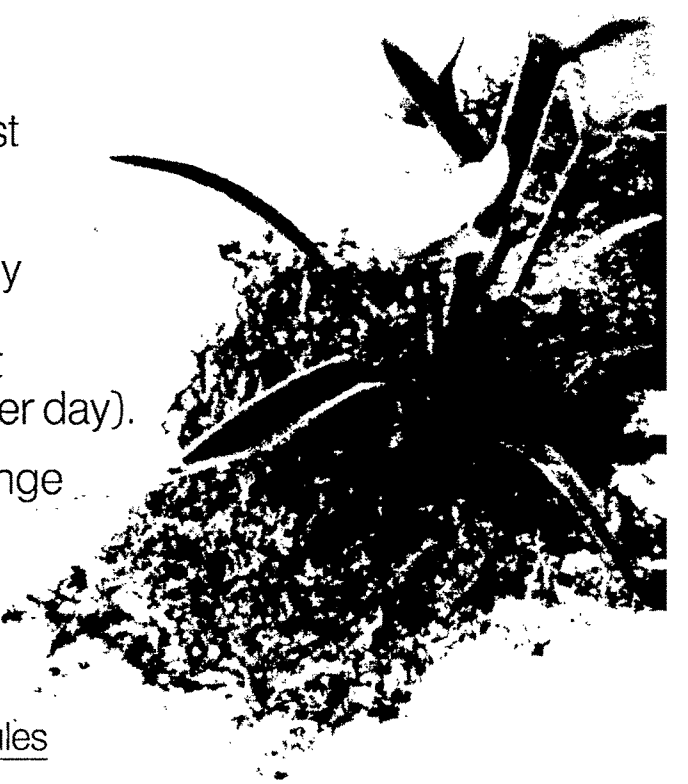
Ritalin® (methylphenidate)



ONLY WHEN MEDICATION IS INDICATED

C I B A

A CHANGE FOR THE BETTER IN CLINICAL DEPRESSION

Even before optimal antidepressant effect becomes evident, Sinequan (doxepin HCl) can help the clinically depressed patient sleep better and feel less anxious. That's because Sinequan provides prompt sedative activity and marked antianxiety relief, in addition to its significant antidepressant effect.

But that's not all. Its incidence of cardiovascular effects is low. Tachycardia and hypotension are infrequent. (Drowsiness is the most common side effect.) Moreover, Sinequan, unlike other tricyclic antidepressants, does not generally affect the activity of guanethidine and similarly acting compounds at usual clinical doses (75-150 mg. per day).

Sinequan—it could mean a change for the better.

SINEQUAN®
DOXEPIN HCl

25-mg., 50-mg. and new 100-mg. capsules

(See Brief Summary on following page for information on adverse reactions, contraindications, warnings and precautions.)

Pfizer **LABORATORIES DIVISION**
PFIZER INC.

A CHANGE FOR THE BETTER IN CLINICAL DEPRESSION

SINEQUAN®
DOXEPIN HCl

25-mg., 50-mg. and new 100-mg. capsules

BRIEF SUMMARY
Sinequan® (doxepin HCl) Capsules

Contraindications. Sinequan is contraindicated in individuals who have shown hypersensitivity to the drug.

Sinequan is contraindicated in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* Sinequan has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: The use of Sinequan in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with Sinequan. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan, however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan does exert a significant blocking effect. In addition, Sinequan (doxepin HCl) was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects*: Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Sinequan is available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's).

Assaultive and belligerent?

Cooperation often begins with HALDOL® (haloperidol)

a first choice for starting therapy

Acts promptly to control aggressive, assaultive behavior

Several studies have reported the special effectiveness of HALDOL (haloperidol) in controlling disruptive and dangerously assaultive behavior.[1-3] Even the number of violent assaults committed by a group of criminal psychotics "resistant to maximal doses of phenothiazines" was reduced substantially during treatment with HALDOL.[1] Symptom control can be achieved rapidly, frequently within a few hours when the intramuscular form is used for initial control of acutely agitated psychotic states.[2-4]

Usually leaves patients relatively alert and responsive

Although some instances of drowsiness have been observed, marked sedation with HALDOL (haloperidol) is rare. In a report on a study with criminal psychotics the investigator states, "The patients remained alert and more amenable to psychotherapeutic intervention."[1] Another investigator reports that HALDOL "normalizes" behavior and produces a sensitivity to the environment that allows more effective use of the social milieu and the therapeutic community.[5]

Reduces risk of serious adverse reactions

HALDOL (haloperidol), a butyrophenone, avoids or minimizes many of the problems associated with the phenothiazines. Hypotension is rare and severe orthostatic hypotension has not been reported. There is also less likelihood of adverse reactions such as liver damage, ocular changes, serious hematologic reactions and skin rashes.

The most frequent side effects of HALDOL (haloperidol)—extrapyramidal symptoms—are usually dose-related and readily controlled.

HALDOL®
(haloperidol)

a first choice for starting therapy

Now available: 10 mg. Tablets – For convenience in high-dosage regimens.

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: HALDOL (haloperidol) is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 6/74

McNEIL McNeil Laboratories, Inc.
Fort Washington, Pa. 19034

DEPUTY DIRECTOR FOR YOUTH CARE
FATHER FLANAGAN'S BOYS' HOME

Applications are being accepted for the position of Deputy Director for Youth Care at Father Flanagan's Boys' Home, located in Omaha, Nebraska. The Deputy Director will report to the Executive Director of the Home and will be responsible for the management, integration, coordination, and control of all aspects of the child care program. He/She will be responsible for the following types of services: Admission, evaluation, and clinical services; Residential services; Student activities and government; Program planning and evaluation; and, Spiritual life activities.

Applicants should have substantial managerial experience in human service organizations, preferably in the child care field. Also, applicants should have advanced degrees in an academic area related to youth care. Salary will be commensurate with experience and capabilities, ranging from $28,800 to $43,200.

All applications should be sent to:

Dr. Ronald A. Feldman, Chairman
Search Committee for Deputy Director
for Youth-Care
Suite 111 — 8401 West Dodge Road
Omaha, Nebraska 68114

PSYCHIATRISTS . . .

Board eligible and board certified to fashion positions within innovative programs. Positions in the Triage-Crisis Intervention Program, Acute Psychiatry Program and Intermediate Psychiatry Program, Out-patient Psychiatry Program, Research and formal teaching opportunities are available. Medical school affiliation with medical students and residents training within each program. Salaries from $28,287 to $34,827 based upon qualifications. No discrimination in employment.

Apply to: Chief of Psychiatry
VA Hospital
Downey, Illinois 60064

THE AMERICAN JOURNAL OF PSYCHIATRY

NOW, your journals can become an attractive permanent part of your professional library. These famous Jesse Jones volume files, especially designed to keep your copies orderly, readily accessible for future reference—guard against soiling, tearing, wear or misplacement of copies. These durable files will support 150 lbs. Looks and feels like leather and is washable. The 23-carat gold lettering makes it a fit companion for the most costly binding.

Reasonably priced, too. Only $4.25, 3 for $12.00, 6 for $22.00 POSTPAID U. S. A. ORDERS ONLY. Satisfaction unconditionally guaranteed or your money back.

DIRECTOR
EMERGENCY SERVICES

The West Philadelphia Community Mental Health Consortium, Inc., a large established Community Mental Health Center in Philadelphia is seeking a creative Board Eligible or Certified Psychiatrist to direct its Emergency Services. Combination of administrative and clinical responsibilities for a 24 hour Emergency Service and Home Visiting Team, liason with other Service Directors, and participation in top management team.

Position carries possible affiliation with Department of Psychiatry of University of Pennsylvania, depending on qualifications. Competitive salary, plus excellent fringe benefits.

Contact Herbert Diamond, M.D., Medical Director, West Philadelphia Community Mental Health Consortium, P.O. Box 8076, Philadelphia, Pennsylvania 19101.

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety or agitation with depression

Triavil® 4-25

Each tablet contains
4 mg perphenazine and
25 mg amitriptyline HCl

a formulation particularly suited to psychiatric practice when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl

TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and that the full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude, muscle weakness, mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastic distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of tricyclic antidepressant poisoning. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

"Insomnia often occurs when a patient is troubled by a problem for which he is not prepared."

Passing on a valid point:
a sense of continuity from one generation of psychiatrists to another.

Insomnia is a problem for which NOLUDAR® 300 (methyprylon) Ⓒ III is prepared

Effectiveness. A single capsule of Noludar 300 generally provides an uninterrupted night's sleep of from 5 to 8 hours duration. Sleep is usually induced within 45 minutes.

Safety. While Noludar 300 is a Schedule III controlled medication, it is not a barbiturate or a methaqualone. Administer with caution to individuals known to be addiction-prone or those whose history suggests they may increase the dosage on their own initiative.

Reliability. Noludar is a reliable hypnotic in use for over 19 years. It can help the insomniac patient sleep and wake refreshed to meet the new day, usually with little or no morning-after "hang-over." At recommended dosages (one capsule before retiring), paradoxical excitation has been rare.

Before prescribing, please consult Complete Product Information, a summary of which follows:

INDICATION: As a hypnotic for relief of insomnia of varied etiology.

CONTRAINDICATIONS: Patients with known hypersensitivity to the drug.

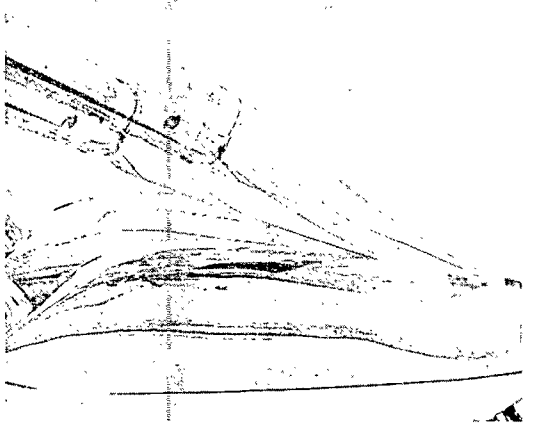
WARNINGS: Caution patients about combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness, such as operating machinery or driving a motor vehicle shortly after ingesting the drug.

Physical and Psychological Dependence: Physical and psychological dependence have been reported infrequently. Withdrawal symptoms, when they occur, tend to resemble those associated with withdrawal of barbiturates and should be treated in a similar fashion. Use caution in administering to individuals known to be addiction-prone or those whose history suggests they may increase the dosage on their own initiative. Repeat prescriptions should be limited without adequate medical supervision.

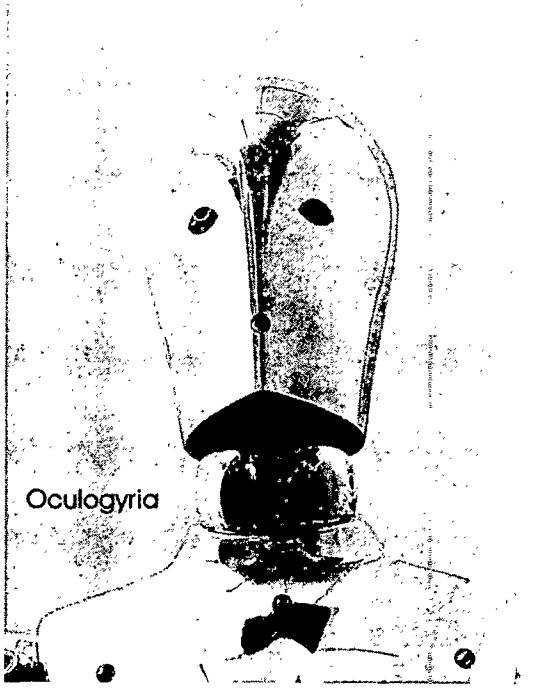
Usage in Pregnancy: Weigh potential benefits in pregnancy, during lactation, or in women of childbearing age against possible hazards to mother and child.

Usage in Children: Not recommended in children under 3 months of age.

PRECAUTIONS: Total daily intake should not exceed 400 mg, as greater amounts do not significantly increase hypnotic benefits. Observe usual precautions in hepatic or renal disorders. Perform periodic blood counts if used repeatedly or over prolonged periods.



ADVERSE REACTIONS: At recommended dosages, there have been rare occurrences of morning drowsiness, dizziness, mild to moderate gastric upset (including diarrhea, esophagitis, nausea and vomiting), headache, paradoxical excitation and skin rash. There have been a very few, isolated reports of neutropenia and thrombocytopenia; however, the evidence does not establish that these reactions are related to the drug.



SUPPLIED: *Capsules* containing 300 mg methyprylon. *Tablets* containing 200 mg or 50 mg methyprylon.

■ ARTANE® Trihexyphenidyl HCl. It can prevent or reverse the sometime dehumanizing extrapyramidal effects of the antipsychotic drugs. ■ But without the drug buildup potential of cumulative action anticholinergics. ■ And at lower cost.

Tablets:
2 mg and 5 mg

Elixir:
2 mg/5 cc with 0.08% methylparaben, 0.02% propylparaben and 5% Alcohol as preservatives.

SEQUELS®
Sustained Release Capsules: 5 mg

Tablets and Elixir: Indications: FDA has evaluated this drug as Effective as an adjunct in the therapy of the indications listed below under SEQUELS.

***INDICATIONS FOR ARTANE SEQUELS:** Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms of parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for the use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine and phenothiazines.

WARNING:
Patients to be treated should have a gonioscope evaluation and close monitoring of intraocular pressures at regular periodic intervals.

Precautions: Patients with cardiac, liver or kidney disorders or with hypertension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated. Periodic gonioscopic evaluations in all patients to be treated with this or any related drug is advised.

Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilatation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache. Angle-closure glaucoma due to long-term treatment with this drug has been reported.

AMERICAN PSYCHIATRIC ASSOCIATION

UNIVERSITY COLLEGE OF MEDICINE
LIBRARY

You know what to expect:

DEPENDABILITY

For effective management of psychotic symptoms

- unsurpassed clinical experience
- widely researched and documented
- 18 dosage forms and strengths for maximum flexibility

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol.

©1967, 1968, 1969 SmithKline Corporation

May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100 and Single Unit Packages of 100. Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50 and Single Unit Packages of 100. Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate, 30 mg./ml. and 100 mg./ml.

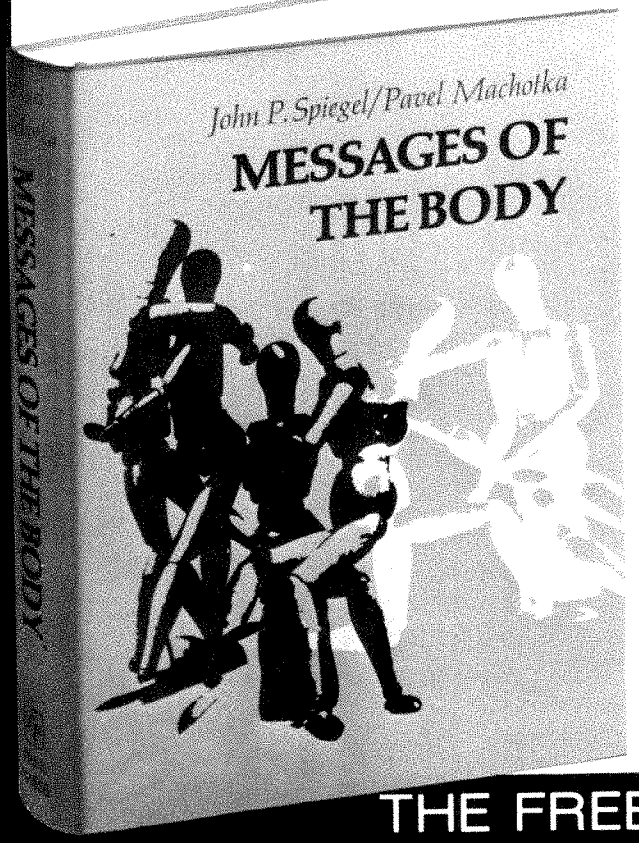
MESSAGES OF THE BODY



John P. Spiegel, Brandeis University, and Pavel Machotka, University of California, Santa Cruz

How do we communicate without speech? This question is intensively explored in *Messages of the Body*—one of the first truly scientific studies of body language. Based on wide-ranging research in aesthetics, the behavioral sciences and the visual arts, the book proposes a powerful new cognitive theory of body messages and describes a series of experiments testing parts of the theory.

Profusely illustrated with over 50 pages of photographs and line drawings that are an essential part of the text, this book provides not only a novel approach to the field, but also provides concepts and methods that will stimulate new experiments and applications of these insights.

"This unique study . . . will become a classic reference and build a needed bridge between the arts and the science of man."
—Jerome Kagan, Harvard University

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

Tofranil-PM®
imipramine pamoate

Capsules* of 150, 125, 100 and 75 mg.

One capsule lasts from bedtime to bedtime.

For single-dose therapy in depression when the dosage is established.

- simple enough dosage regimen to help avoid missed doses.
- while daily dosage ranges from 75 to 300 mg., the 150-mg. capsule may be the most effective daily dose for many patients.
- becomes part of the regular bedtime routine—making it easier to establish a more reliable pattern of self-medication.
- safety/efficacy ratio equivalent to divided daily doses.
- provides a full range of single daily dosage strengths to facilitate increasing or gradually decreasing medication.
- saves time and cost of dosage administration in the hospital.

Please read the prescribing information for details of usage, precautions, warnings, contraindications, adverse experiences, and dosage recommendations. A summary of this information appears on the following page.

*Each capsule contains imipramine pamoate equivalent to 150, 125, 100 or 75 mg. of imipramine hydrochloride.

Tofranil-PM® Geigy
imipramine pamoate

One capsule lasts from bedtime to bedtime.

Tofranil-PM®
brand of imipramine pamoate
Tofranil®
brand of imipramine hydrochloride USP

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil, brand of imipramine hydrochloride, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

- —patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
- —patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
- —hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
- —patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
- —patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Usage in Children: Pending evaluation of results from clinical trials in children, Tofranil, brand of imipramine hydrochloride, is not recommended for treatment of depression in patients under twelve years of age.

Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as operating an automobile or machinery, the patient should be cautioned accordingly.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil, brand of imipramine hydrochloride, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil, brand of imipramine hydrochloride, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine hydrochloride should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: Lower dosages are recommended for elderly patients and adolescents. Lower dosages are also recommended for outpatients as compared to hospitalized patients who will be under close supervision. Dosage should be initiated with Tofranil, brand of imipramine hydrochloride, at a low level and increased gradually, noting carefully the clinical response and any evidence of intolerance. Following remission, maintenance medication may be required for a longer period of time, at the lowest dose that will maintain remission.

Once-a-day maintenance dosage can be provided with Tofranil-PM, brand of imipramine pamoate, capsules if this dosage has been established as explained above. This dose may be given at bedtime. For the occasional patient who manifests stimulation and insomnia with this dosage regimen, the capsules may be given in the morning.

Parenteral administration should be used only for starting therapy in patients unable or unwilling to use oral medication. The oral form should supplant the injectable as soon as possible.

How Supplied: Tofranil, brand of imipramine hydrochloride: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg.; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.

Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.) (B) 98-146-850-P (2/74)

For complete details, including dosage and administration, please refer to the full prescribing information.

SEXUAL DYSFUNCTION: A BEHAVIOR THERAPY WORKSHOP

Emphasizing short term treatment techniques for use by practicing physicians and mental health professionals

Topics Include:

Taking a comprehensive sex history
Treatment of female orgasmic dysfunction
Treatment of male impotence
Sexual communication training
Facilitating sexual arousal
Enhancing sexual arousal
Sexual anxiety reduction
Desensitization of a sexual phobia
The pubococcygeal muscle & the female orgasm
Dealing with sexual mythology
Assertive training for the bedroom
Taking a brief sex history
Treatment of ejaculatory incompetence
Pleasuring
Relaxation training
Dual-sex-team approach
Intensive treatment weekends
Humor training
Changing the bedroom environment
Counseling the aging male & female
Counseling the homosexual — case studies
Vaginismus
Premature ejaculation — two treatment modes
Pre-coital counseling
Counseling cardiac patients — what not to say
Dyspareunia
Theology and Human Sexuality

The use of films in sex therapy — films will be shown
Optional small group Sexual Attitude Reassessment Workshop with films

Philadelphia Conference, April 12-13, 1975 — sponsored by Behavior Therapy Unit, Department of Psychiatry, Temple University Medical School, Philadelphia, PA

For information, please contact Ms. B. J. Foster, Room 702, Temple Department of Psychiatry, c/o E.P.P.I., Henry Ave., Philadelphia, PA 19129. Telephone: 215-438-4298, x. 54.

The Princeton Center for Behavorial Consultation will sponsor this program in:

Atlanta, April 18-19, 1975
(Follows the sectional meeting of the American Urological Association)

Boston, May 3-4, 1975
(Precedes the national meeting of the American Society of Obstetricians and Gynocologists)

Chicago, May 10-11, 1975

Miami Beach, May 16-17, 1975
(Follows the American Urological Association Convention)

For infomation on these workshops, please write to: Ms. Debora Phillips, Princeton Center for Behavioral Consultation, Room 202, 53 Wilton Street, Princeton, NJ 08540

The March 1975 issue of

The American Journal of Psychiatry

will feature

- The 1975 Annual Meeting
  Preliminary Program

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized, and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In clinically significant depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD) helps establish early therapeutic rapport

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. May enhance response to alcohol and effects of barbiturates and other CNS depressants. Possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent administration with electroshock therapy may increase hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue drug several days before elective surgery, if possible. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of other tricyclic antidepressant poisoning.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

For more detailed information, consult your MSD representative or see full prescribing information.
Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

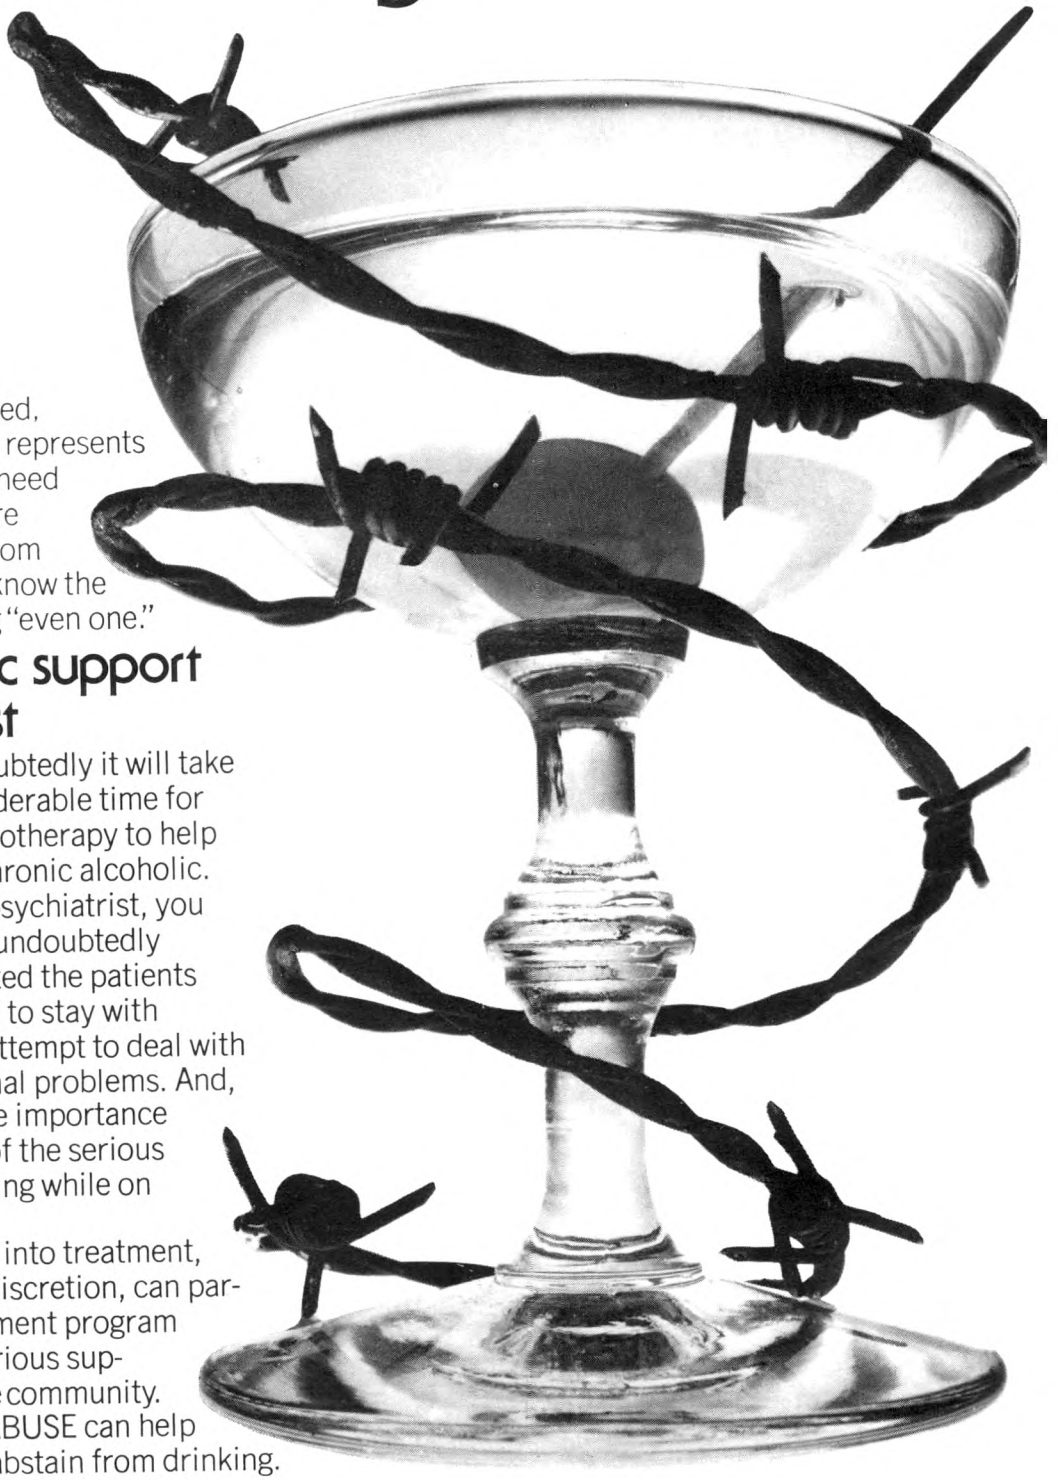
addendum

MSD
MERCK SHARP & DOHME

MSD 26 5 mg (orange)

MSD 47 10 mg (yellow)

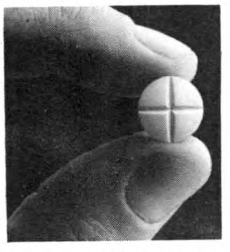
The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.



In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.

When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.



(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

ANTABUSE: "Social security" for the alcoholic who wants to stop drinking...

The temptation is resisted, ANTABUSE (disulfiram) represents the security alcoholics need in any situation. They are better able to abstain from drinking because they know the consequences of taking "even one."

until psychiatric support can do the rest

Undoubtedly it will take considerable time for psychotherapy to help the chronic alcoholic. As a psychiatrist, you have undoubtedly selected the patients who are best motivated to stay with ANTABUSE while you attempt to deal with the underlying emotional problems. And, of course, you know the importance of reminding patients of the serious consequences of drinking while on ANTABUSE.

Once sober, and well into treatment, the alcoholic, at your discretion, can participate in a total treatment program which makes use of various supportive resources in the community. In the meantime, ANTABUSE can help the chronic alcoholic abstain from drinking.

BRIEF SUMMARY
(For full prescribing information, see package circular.)

ANTABUSE® (disulfiram) in Alcoholism

INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)

CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, e.g. cough syrups, tonics, and the like, should not be given ANTABUSE.

ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.

The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.

THE ANTABUSE-ALCOHOL REACTION: ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.

The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.

DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.

Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.

It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.

Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.

CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.

USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE (disulfiram) should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.

PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)

Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.

Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)

Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.

In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.

Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.

There have been reports of polyneuritis and peripheral neuritis, and rare instances of optic neuritis. One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.

DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.

INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.

MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.

NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE (disulfiram), report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.

DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years

TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.

However, where a test reaction is deemed necessary, the suggested procedure is as follows:

After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (½ oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.

MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.

HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100. No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000.

ANTABUSE®

BRAND OF DISULFIRAM

May enhance other remedial efforts in treating MBD[1]
ONLY WHEN MEDICATION IS INDICATED
Ritalin®
(methylphenidate)

Ritalin...of proven value when used as part of a complete therapeutic and remedial MBD program

More than a decade of clinical experience shows that Ritalin helps improve ratings of behavior, attentiveness, performance IQ, motor control, and speech productivity in children with Minimal Brain Dysfunction (MBD).[1-5]

Currently a drug of choice in many MBD situations,[6] Ritalin can play an important part in the total rehabilitation program of the MBD child. And proper management is essential to the overall (educational, social, and emotional) development of the child's potential.

Dosage should be periodically interrupted in the presence of improved motor coordination and behavior. Often, these interruptions reveal that the child's behavior shows some "stabilization" even without chemotherapy, permitting a reduction in dosage and eventual discontinuance of drug therapy.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ℗
(methylphenidate hydrochloride)
TABLETS

INDICATION
Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)
Special Diagnostic Considerations
Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.
Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.
Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.
CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.
WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.
Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.
Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC, differential, and platelet counts are advised during prolonged therapy.
ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy.
Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.
In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.
DOSAGE AND ADMINISTRATION
Children with Minimal Brain Dysfunction (6 years and over)
Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.
If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.
Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.
Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.
HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak blister units of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

Ritalin®(methylphenidate)

ONLY WHEN MEDICATION IS INDICATED

CIBA

Agitated and hyperactive?

Consider the advantages of starting him on HALDOL® (haloperidol)

Acts promptly to control agitation

HALDOL haloperidol appears to be particularly effective in calming mania and psychomotor agitation.[1-7] Symptom control is achieved rapidly, with many patients showing distinct improvement in a few days to a week[4,5]—frequently within a few hours when the intramuscular form is used for initial control of acutely agitated psychotic states.[1,6,7]

Usually leaves patients relatively alert and responsive

Although some instances of drowsiness have been observed, marked sedation with HALDOL haloperidol is rare. In fact, this drug has been reported to increase activity in some underactive patients, while in hyperactive patients it usually reduces activity to a normal level without somnolence. HALDOL haloperidol has been found to "normalize" behavior and produce a sensitivity to the environment that allows more effective use of the social milieu and the therapeutic community.[8]

Reduces likelihood of certain adverse reactions

HALDOL haloperidol, a butyrophenone, avoids or minimizes many of the problems associated with the phenothiazines. The most commonly noted side effects of HALDOL haloperidol—extrapyramidal reactions—are usually dose-related and readily controlled with antiparkinson drugs.

Transient hypotension occurs rarely; severe orthostatic hypotension has not been reported. HALDOL haloperidol is also unlikely to cause hepatic damage, serious hematologic reactions, photosensitivity reactions and skin rashes. Ocular damage and pigmentation changes have not been reported.

HALDOL®
(haloperidol)
tablets/concentrate/injection

highly specific control of disordered and disruptive behavior

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

©McNeil Laboratories, Inc., 1975

HALDOL®
(haloperidol)
tablets/concentrate/injection

highly specific control of disordered and disruptive behavior

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

An undetectable, tasteless liquid concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Indications: HALDOL haloperidol is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's syndrome.

Contraindications: HALDOL haloperidol is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL haloperidol in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of haloperidol orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL haloperidol, decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL haloperidol may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL haloperidol should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL haloperidol may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant antiparkinson medication is required, it may have to be continued after HALDOL haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson agents, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of antiparkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long-term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed. 9/74

1975 APA Appointment Books Desk and Pocket-sized

The "week-at-a-glance" Desk Appointment Book and the Pocket-sized version, published by the American Psychiatric Association, provide a quick and organized reference to your weekly engagements. As an added feature, it contains a comprehensive list of organizations and agencies of interest to psychiatrists and mental health professionals—in most cases director's name, address, phone number and date of forthcoming annual meeting are included. Also, there's a section to keep important phone numbers.

The Pocket-sized Appointment Book is 4" × 7 1/2", which is small enough to tuck inside your jacket, purse, suitcase or briefcase.

Desk: $5.00 ea.
Pocket: $3.00 ea.
Both: $7.00

Order 10 or more books for your colleagues or as gifts for your friends and take advantage of the 10% discount. Desk: $4.50 ea., Pocket-size: $2.70 ea. (15% discount for 100 or more copies)

Please send me

Medical Behavioral Science

A new collection of readings edited and introduced by **Theodore Millon,** Ph.D., Professor and Director, Behavioral Science Programs, University of Illinois College of Medicine.

This unique anthology fills a long-standing gap in the literature, defining the scope of a highly interdisciplinary field. Fifty-four articles by over 60 eminent authorities provide the reader with a guide to the psychosocial influences that shape his patients' lives. Students will find it an ideal preparation for Part 1 of their National Boards.

Key concepts in biobehavioral, psychobehavioral, interbehavioral and sociobehavioral medicine offer a logical progression of perspectives. Dr. Millon has compiled a balanced book that avoids emphasis on any one discipline. "The time for tangible growth and development of medical behavioral science has indeed come, and this book is a fine reflection of substantive maturation." *(—from the Foreword by Dr. Melvin Sabshin).*

656 pp. $14.95.

W. B. Saunders Company
West Washington Square, Philadelphia, Pa. 19105

Dear Doctor:

What happens to your patient when he/she has completed their period of intensive psychiatric hospitalization?

Do you feel that he is ready to assume the responsibilities of daily living in an unstructured environment? Or do you feel certain that a period of time with supervision would ensure a more stable adjustment to family life?

There is just such a facility.
1. Nursing supervision is available.
2. Recreational therapy is creative and challenging.
3. Dining is superb — Therapeutic diets available.
4. Companionship.
5. Charming decor.

A CHANGE FOR THE BETTER IN CLINICAL DEPRESSION

Even before optimal antidepressant effect becomes evident, Sinequan (doxepin HCl) can help the clinically depressed patient sleep better and feel less anxious. That's because Sinequan provides prompt sedative activity and marked antianxiety relief, in addition to its significant antidepressant effect.

But that's not all. Its incidence of cardiovascular effects is low. Tachycardia and hypotension are infrequent. (Drowsiness is the most common side effect.) Moreover, Sinequan, unlike other tricyclic antidepressants, does not generally affect the activity of guanethidine and similarly acting compounds at usual clinical doses (75-150 mg. per day).

Sinequan—it could mean a change for the better.

SINEQUAN®
DOXEPIN HCl
25-mg., 50-mg. and new 100-mg. capsules

(See Brief Summary on following page for information on adverse reactions, contraindications, warnings and precautions.)

PFIZER INC.

© 1974, Pfizer Inc.

A CHANGE FOR THE BETTER IN CLINICAL DEPRESSION

SINEQUAN®
DOXEPIN HCl

25-mg., 50-mg. and new 100-mg. capsules

BRIEF SUMMARY
Sinequan® (doxepin HCl) Capsules

Contraindications. Sinequan is contraindicated in individuals who have shown hypersensitivity to the drug.

Sinequan is contraindicated in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* Sinequan has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: The use of Sinequan in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with Sinequan. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan, however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan does exert a significant blocking effect. In addition, Sinequan (doxepin HCl) was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestina reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Sinequan is available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's).

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

ELAVIL®
(AMITRIPTYLINE HCl|MSD)
useful in many therapeutic settings

In the psychiatrist's office. Whatever other therapeutic facilities have been developed, the psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations.

In the general hospital. The general hospital today usually provides a psychiatric unit where depressed patients may be treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

In the outpatient clinic. With follow-up treatment often necessary for three months or longer, ELAVIL is highly effective in maintaining relief, especially in patients who responded well to higher doses while hospitalized. As a result, these patients may continue to function in their daily activities.

In the mental hospital. Here where severely depressed patients present challenges for psychiatrist and staff alike, the usefulness of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

In the community mental health center. A remarkable innovation in the field of modern psychiatry, this center offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

Should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

In many therapeutic settings—one proven antidepressant

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP DOHME

addendum

ELAVIL®
(AMITRIPTYLINE HCl | MSD)
dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for initial therapy in adult outpatients. Starting dosage is usually 75 mg daily in divided doses or 50 to 100 mg once a day at bedtime. If necessary, this dosage may be increased gradually to a total of 150 mg a day. When doses are divided, dosage increases are made preferably in the late afternoon or at bedtime. A sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be advantageous whenever higher dosages are required, or when the single daily dose is given at bedtime. The 50-mg tablet may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of tricyclic antidepressant poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

FIRST INTERNATIONAL SYMPOSIUM AND WORKSHOP ON SHORT-TERM DYNAMIC PSYCHOTHERAPY

March 19-22, 1975

Sponsored by:

THE SHORT-TERM PSYCHOTHERAPY UNIT
of the
DEPARTMENT OF PSYCHIATRY
THE MONTREAL GENERAL HOSPITAL
and the
DEPARTMENT OF PSYCHIATRY
McGILL UNIVERSITY

With the participation of:
Dr. David Malan, Consultant, Tavistock Clinic, London, England

Dr. Peter Sifneos, Professor of Psychiatry, Harvard Medical School, Boston

To be held in Montreal, Quebec, Canada

Audiovisual facilities are used throughout the four-day symposium and workshops. The aim is to demonstrate by use of videotapes the evaluation, criteria for selection of patients, techniques, process, and outcome of short-term dynamic psychotherapy.

For information and application forms, please write:
H. Davanloo, M.D.
First International Symposium and Workshop
On Short-Term Dynamic Psychotherapy
P.O. Box 342
Place Bonaventure
Montreal, Quebec, Canada H5A 1B5

The Department of Education of the

MENNINGER FOUNDATION

offers

Spring and Summer Workshops 1975
In Family Therapy

Two-and-one-half day Workshops:
March 6-8, 1975 or
April 10-12, 1975 Tuition: $150
and/or
Five day Workshops:
May 5-9, 1975
June 2-6, 1975
June 23-27, 1975 Tuition: $225

For the beginner and experienced practitioner. Family therapy exercises, family role playing, family sculpting, and analysis of family problems. Small group discussions of family systems theories, structural approaches, family diagnostic interviews, family communication and the therapist's use of self. Video tape illustrations of family treatment. Participants are encouraged to bring their own audio and/or video tapes for discussion.

Direct inquiries to: Mr. Arthur Mandelbaum, Director, Workshops in Family Therapy and Director, Family Therapy Staff Training Program, The Menninger Foundation, P.O. Box 829, Topeka, Kansas 66601

THERE IS NOW A NEW DIMENSION IN THINKING ABOUT HUMAN BEINGS!

C. David Jones, M.D., a world recognized medical scientist, listed in the Dictionary of International Biography, teaches at the University of Chicago Medical School and maintains his own large practice utilizing hominological therapy with outstanding success. He has written a book called: HOMINOLOGY — PSYCHIATRY'S NEWEST FRONTIER.

For the first time *moral values* are clearly integrated into concepts of mental health, education, international affairs and physical disease. All of these concepts are meaningfully tied together in a manner that is easy and pleasant to read yet offers principles, ideas and guidelines that can be readily utilized and immediately applied.

Dr. Jones' book is truly revolutionary in its innovations making other concepts in the field of community mental health, psychotherapy and diagnosis obsolete. The concensus of those who have previewed it is that "no one in the field of mental health should be without it!"

C. David Jones, M.D. F.R.S.H.

First day in the hospital and all efforts will be directed toward returning her to the community.

For psychotic patients with mixed anxiety-depression, Mellaril has been found useful to help patients participate more fully in the entire therapeutic program. Continued medication with Mellaril is often basic to helping patients prepare for and participate in outpatient treatment programs that bridge the gap between hospital and community.

With Mellaril, patients are generally alert and in better contact with reality and can more fully benefit from the entire therapeutic program. (In the hospital or out, even though Mellaril produces only minimal sedative effect, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, a distinctive feature of Mellaril is that extrapyramidal stimulation —notably pseudoparkinsonism—is minimal.

MELLARIL®

(THIORIDAZINE)

TABLETS: 25 mg., 50 mg., 100 mg., 150 mg., and 200 mg. thioridazine HCl, U.S.P.

helps in the management of psychotic patients with mixed anxiety-depression

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

THE AMERICAN JOURNAL OF PSYCHIATRY

Psychiatric Training and Practice in the People's Republic of China

BY PHILIP D. WALLS, M.D., LICHUN HAN WALLS, PH.D., AND DONALD G. LANGSLEY, M.D.

Improved political relations between the United States and the People's Republic of China have led to closer contact in many areas. The authors trace the development of psychiatric training and practice in China with emphasis on the years after 1949. Since then, China has expanded psychiatric services to meet the needs of a vast population and has developed a theoretical approach to psychiatry that emphasizes sociopolitical factors. Additional information given to the authors in 1973 by psychiatrists in Nanking and Shanghai is presented and correlated with reports by other recent visitors to the People's Republic of China.

ALTHOUGH A NUMBER of American physicians have visited the People's Republic of China since 1972, when travel restrictions were relaxed, there are few firsthand reports about psychiatry and mental hospitals in China. Two of us (P.D. Walls and L.H. Walls) visited China from August 8 to October 21, 1973, to gather and exchange information about medical and psychiatric education and practice. L.H. Walls, a biochemist, is a native of China and is fluent in Mandarin Chinese, as well as being familiar with psychiatric terminology and practice in the United States by virtue of her marriage to a psychiatrist.

The itinerary included Canton, Shanghai, Hangchow, Nanking, and Peking and a visit to a medical school in each of these cities. We met with practicing psychiatrists in Nanking, and in Shanghai we were able to visit psychiatrists and to tour the Shanghai Psychiatric Institute. Visits to a commune near Shanghai and to one near Peking were also arranged, as were visits to various factories, hospitals, clinics, a nursery, a kindergarten, a youth recreation center, and many exhibitions and sights in these cities. All such arrangements were made in each city through local offices of the International Travel Agency of the People's Republic of China, whose agents were courteous and helpful in the handling of so many requests. Our trip was not sponsored by any groups inside or outside China.

We submitted requests in each city visited, and although it was not convenient for all of them to be granted, we received a great deal of cooperation and enjoyed considerable freedom. We were always permitted to take notes during interviews, and we routinely received permission to tape-record the interviews. The tapes were transcribed verbatim into English as soon as possible after each interview in order to avoid misquotations and imperfect recollection. We conducted interviews with groups rather than individuals. At a hospital the group might include an administrator (usually the chairman of the Revolutionary Committee of the hospital), several physicians, and nurses. After introductory remarks had been presented, there was a tour of the facilities and an exchange of questions and answers. The meetings usually lasted a whole morning or afternoon, but only one meeting could be arranged with any one group. This restriction must be due in part to the increasing numbers of visitors, who would consume too much of the working staffs' time if all received repeated appointments.

PSYCHIATRY IN TRADITIONAL MEDICINE

Mental illness has been recognized in China for over 2,000 years. Paralysis, epilepsy, and hysteria were mentioned in early texts and were described as maladies of "wind" (1). In China the concepts of "breath" and "wind" are still popularly believed to affect health. "Breath" is comparable to very early Greek and Roman notions of "psyche" (from the Greek *psychein*, to breathe, to blow) and of "spirit" (from the Latin *spirare*, to breathe). Specialization in psychiatry existed in the

At the time this work was done, Dr. Philip Walls was a resident in psychiatry, University of California, Davis School of Medicine, Sacramento, Calif.; and Dr. Lichun Walls was formerly Assistant Professor of Chemistry, California State University at Fresno, Calif. Dr. Philip Walls is currently Clinical Associate, National Institutes of Health, St. Elizabeths Hospital, Washington, D.C., and Dr. Lichun Walls is Assistant Professor of Chemistry, Morgan State College, Baltimore, Md. Dr. Langsley is Professor and Chairman, Department of Psychiatry, University of California, Davis School of Medicine. Address reprint requests to Dr. Philip Walls, 3605 Farness Dr., Temple Hills, Md. 20031.

11th century, when one Chinese medical school had established a separate department of nervous and mental disorders with 30 students.

In the first decade of the 17th century, observation and classification of mental disorders had progressed to the extent that a famous doctor of traditional Chinese medicine, Wang K'en-T'ang, wrote on insanity, mania, and fits (2). His description of insanity fits schizophrenia very well, and mania and grand mal seizures are also well characterized. Wang noted that the insane got no better even after years of illness. He believed that these patients had "wind in the mind," and he offered the explanation that "those with frustrated ambition are likely to be so affected." Chang Chieh-Pin, a contemporary of Wang's, pointed out that insanity resulted in progressive deterioration. Chang also alluded to the phenomenon of febrile delirium, and he commented on the lack of childhood cases of insanity (2). Acupuncture, herbal preparations, exercises of various kinds, and other traditional methods were used in the treatment of mental illness. However, little change in classification or treatment seemed to develop inside China after the 17th century.

Some of the reasons for this slow development of mental health sciences may be related to factors described by Ilza Veith (3). She suggested that the Chinese were traditionally less concerned about mental illness than the Europeans, although, as Bowman (4) has confirmed, mental illness was as common in China as in other countries. The tradition of respect for elders (filial piety) and the practice of using go-betweens in potentially embarrassing situations (part of the tradition of saving face) may have done much to lessen the impact and importance of mental disturbance in individual cases. Veith (3) also pointed out that in China mental illness was never associated with any religious stigma, such as that which stimulated much controversy and theoretical discussion in the West.

PSYCHIATRY IN MODERN TIMES (1900–1949)

Western psychiatric ideas were introduced in China about 75 years ago when the first Western-style mental hospital to receive patients was established in 1897 in Canton province. A course in psychiatry was taught at the Peking Union Medical College for the first time in 1922. The practice of psychiatry continued to make slow gains over the 50 years from the establishment of the first asylum for the insane to the inauguration of the People's Republic of China in 1949 (5). At that time only four psychiatric hospitals may have been in operation in all of China (5, 6), with a total capacity of 1,000 to less than 6,000 psychiatric beds and 50 to 60 practicing psychiatrists (4, 6). In regard to psychiatric theory, Cerny (6) has stated that "the teachings of Adolf Meyer were widely accepted in Chinese psychiatry" until 1949.

A report of a brief visit to Peking's An Ding mental hospital provides a glimpse of conditions during the pre-1949 period. This hospital, founded in 1917, was said to have been under police control and neglected for 30 years. There were allusions to experimentation on patients during those years. The hospital had 50 beds in 1949 and was until then being supervised by a non-psychiatric physician who worked only part-time (7).

PSYCHIATRY AFTER 1949

The facilities for psychiatric care and the number of psychiatrists in the People's Republic of China grew rapidly after 1949. The number of beds for psychiatric patients increased from approximately 1,000 to a total of 5,000 in 1955 (8) and 20,000 by 1957 (6). There do not seem to be any data on the number of psychiatric beds after 1957, but a reasonable estimate for the present number is about 60,000. Sixty new mental institutions had been built by 1959, and clinics had been set up in the cities (9). The People's Republic of China has 29 administrative districts at the provincial level on the mainland, and this means an average of about two mental hospitals per province. The municipalities and environs of Shanghai and Peking comprise two of these provinces. In 1957 Fox (10) reported that 600 psychiatric beds were needed for a medical complex in Shanghai; it appears that by 1966, two psychiatric hospitals with a total of 400 beds had been built (11). A recent study quoted a combined total figure of close to 2,000 beds for the two Shanghai hospitals (12). It has been reported that there were a total of 1,500 psychiatric beds in Peking in 1966 (7). An approximation of 2,000 beds per province suggests a figure of about 60,000 beds for the entire country, a number that can also be determined by alternative methods (see following paragraphs).

The meager number of psychiatrists in 1949 grew to 100 in 1952 and to 400 in 1957 (6). Lazure (13) was told in 1959 that there were 15 times the number of psychiatrists as in 1949, or about 900, judging from Cerny's quoted figure (6).

Although no official figures are reported for the number of psychiatrists after 1959, there are several ways to make a current estimate, and each one produces a similar total. One method takes note of the 61 psychiatrists in one of the two Shanghai mental hospitals. This figure was given to us during our visit and to three others (12, 14, 15). If the two Shanghai mental hospitals have similar staffs, there are about 120 practicing psychiatrists in that province and about 3,500 in all 29 provinces. Alternatively, 60 mental institutions were operating in 1959, and if these are now of comparable size to the present Shanghai units, then there are about 3,600 psychiatrists (60 hospitals times 60 psychiatrists is 3,600). Finally, an increase of about 40,000 Western-style physicians was reported in the People's Republic of China from 1949 to 1959 (13, 16, 17), of whom about 900 were psychiatrists, which is a ratio of approximately 1:50. If this ratio held for the next seven years, when 150,000 (18) to 180,000 (7) Western-style doctors were reported, this would suggest a figure of about 3,500 psychiatrists and about 60,000 psychiatric beds, extrapolating from the ratio of psychiatrists to beds in Shanghai.

Due to the reorganization of the Cultural Revolution

in China (1966–1970), few additional doctors have been trained since that time. The first classes of newly trained physicians graduated from some of the medical colleges in 1974 (19).

The 10 years after 1949 showed great growth and change in the mental health field in China. A Society of Neurology and Psychiatry was founded in 1952, and the *Chinese Neurological and Psychiatric Journal* was published from 1955 (6) until the Cultural Revolution. Williams commented that the psychiatrists with whom he spoke "were undoubtedly capable and extremely busy with treatment and teaching" and that "psychiatry is given a place in the medical curriculum quite as high as in most Australian universities" (8). Each of the 50 medical colleges operating in 1960 had departments of psychiatry (13).

A movement to humanize the mental hospitals took place in these early years, especially during the Great Leap Forward of 1958, when an attitude was developed that "humane considerations were to govern the handling of patients" (9). In 1957 chains, isolation, and psychosurgery had been prohibited in Shanghai (6). The use of chains and confinement was discontinued in Peking's An Ding Hospital in 1958 (7). Reviews and reports have provided little knowledge of the day-to-day interaction between doctors, nurses, and their patients. There does not seem to be any information on facilities for the mentally ill from 1959 to 1966 (9). In 1966, however, the physical structure of An Ding Hospital was described. "Not many frills were noted, but then there are very few frills in the Chinese life of today. There was evidence, however, of a good general attitude towards mental illness and there was a sound approach towards rehabilitation" (7, p. 352). There is no indication of whether patients in rural areas were managed similarly or differently from those in the cities.

Most patients classified as needing psychiatric care are referred to regional hospitals for treatment. Inpatient and outpatient care is available. The range of diagnoses given to hospitalized patients is similar to that in this country. From 60 to 80 percent of the patients in three separate reports were classified as schizophrenics (7, 12, 20). The remainder of diagnoses were divided among manic-depressive psychoses, organic brain syndromes, depression, and severe neuroses. The average length of hospital stay varied from three months (7) to 70 to 84 days (14, 21).

Psychiatric Treatment

Treatment for hospitalized patients covers a variety of Western and indigenous methods. For years, persistent efforts have been made to combine Western and Chinese modes of treatments in the field of mental health care as well as in other areas of medicine. Work therapy (6, 13), insulin coma therapy, ECT, sleep therapy, and tranquilizers, but not hypnotherapy or psychosurgery, were used through the early 1960s (6). Chlorpromazine was the principal medication for schizophrenia at An Ding Hospital in Peking in 1966, and depressed patients usually received insulin coma or subcoma therapy. Imipramine had been used previously, but "there had been no great demand" for antidepressants at that time (7). A report of the treatment of mental illness at the Third Peking Hospital in 1972 indicated that schizophrenia was managed with "customary drug therapy" (usually chlorpromazine) and insulin coma therapy and that depression was treated with antidepressant medication (20). Moreover, psychiatrists in Nanking told us that "insulin shock and ECT are used in schizophrenia, insulin more than ECT, if regular measures fail in a given case. It is not used in depression since cases get better with drugs as a rule." According to two reports, insulin coma therapy and ECT have not been used in at least one Shanghai mental hospital since 1970 (12, 15), although this may not yet be the case in general. Currently, the usual treatment for depression seems to be antidepressant medications. Lithium carbonate is used in the treatment of mania (12).

Taipale and Taipale (12) and Ratnavale (14) reported that the maximum daily dosages of chlorpromazine in the treatment of schizophrenia were 200 mg and 250 mg, respectively. We were told that the maximum daily in-hospital dosage was about 600 mg at the Shanghai Psychiatric Institute. The tendency to use increasing doses of phenothiazines in the treatment of schizophrenia seems to have occurred in China as it has in the West.

In addition to drug therapy for mental patients, the Chinese use acupuncture, group therapy in political study groups, counseling by other patients, and appropriate job modification after discharge (22). Psychotherapy is described in various sources. The Chinese literature increasingly discussed "psychogenic factors" in the etiology of mental illness between 1956 and 1966, when Pavlovian psychology was influential in placing emphasis on psychotherapy (9). Heart-to-heart talks between patients and nurses and doctors have become a prominent part of the treatment process (12, 14, 15).

A major therapeutic device is to help patients merge their egos with the collective ego of the state. Patients are presented with the concept of nationalism (22), consisting of exhortation for increased devotion to the community and the state, as a stimulus to generate inner strength with which to overcome mental illness. Point-by-point confrontation of delusional ideas is another part of the interaction between therapists, group members, and the patient (23). Patients may return to the hospital to talk with their nurse (12), or a doctor or nurse may make home visits (22). Group discussions of political works, such as Mao's writings, are held regularly in the hospital with doctors and nurses. Work group discussions of politics are also a regular feature of life for every Chinese citizen, and the use of this mechanism in the hospital is not a novelty.

Sidel visited the "Shanghai Mental Hospital" in 1971 and 1972 (15, 21, 22); Taipale and Taipale visited the "Central Mental Hospital" of Shanghai in 1972 (12); and Ratnavale visited the "Shanghai Psychiatric Institute" in early 1973 (14). Our guide used the name "Shanghai Psychiatric Institute" during our visit, but a more literal translation would be "Shanghai Municipal Psychiatric

Preventive and Treatment Center." A close comparison of the information reported by the four groups showed that all visited the same hospital. This confusion in names is an excellent example of the potential difficulties involved in the translation of even simple matters from Chinese to English. (We will use the name "Shanghai Psychiatric Institute" in further references to this hospital.) Visitors have reported that the institute has 61 psychiatrists on its staff (12, 14, 15), 916 beds (12, 15), and 13 wards (14, 15). We were told that it had 14 wards, 974 beds, and a total staff of 583, including 61 doctors and 213 nurses. This appears to mark an increase in the overall size of the hospital since previous visits.

Little is known about the psychiatric treatment used in outpatient clinics. Cerny (6) reported that acupuncture and other traditional techniques (herbs, exercises, and moxabustion, which is the application of heat to acupuncture points), as well as psychotherapy and pharmacotherapy are used in the treatment of neurotics. Sidel mentioned that chlordiazepoxide, diazepam, acupuncture, herbs, lectures, and individual and group therapy are given to neurotic outpatients (22). Ratnavale wrote that most of the 400 outpatients seen daily at the Shanghai Psychiatric Institute suffered from neurotic and psychosomatic conditions (14), but this contrasts with information from our visit. An introductory speech at the Shanghai Psychiatric Institute included the comment, "Most of the outpatients are those who have received inpatient treatment here. In some cases the outpatients suffer from neurasthenia or epilepsy." However, in still another reference, Chin and Chin reported that 60 percent of the patients treated in the Peking Medical College outpatient mental health department in 1959 were neurasthenics (9). They also pointed out that no statistics are available on the incidence of neurotic illness in the People's Republic of China. Paul T.K. Lin, in a paper presented at the 1973 annual meeting of the American Psychiatric Association, commented that neuroses are practically nonexistent in China (24).

Psychiatric Theory

The theory of mental illness in the People's Republic of China appears to be no less controversial than the statistics, although of course this statement is equally true of Western schools. Pavlovian psychology was a powerful influence up to and probably beyond the Sino-Soviet rift, which took place in 1960. On the one hand, the biological determinants of mental disorder may be stressed in theory and practice, and on the other hand, sociopolitical factors may take the limelight. At different times and in different places, one or the other orientation has been given emphasis. Chin and Chin have outlined the development and progress of this controversy up to 1966 in their excellent book (9).

The controversy continues to the present. In reply to our questions about the etiology of schizophrenia, Nanking psychiatrists cited their belief in genetic and organic origins. Kagan's report from Tientsin (23) seems to show a bias toward social factors there, although the point that biological and social factors are not mutually exclusive is also made. In Shanghai a middle ground seems to be taken. Most patients appeared to be receiving one or more medications or somatic treatments, and all but the most agitated and disorganized patients joined in group therapy. Works of Mao, Marx, and Lenin and current affairs were common topics of conversation. When we asked whether discussions with patients regarding their illness centered around the content of their thinking, the reply was,

> If some patients suffer from delusion, we hold that it may be due to a confusion of the logic in their minds. Therefore, we try to educate them to think in a correct way. We arm their minds with Marxist-Leninist philosophical thinking. Chairman Mao's philosophical works will be assigned for them to read in order to let them know where the correct thinking comes from. So we do not give the patients any sex analysis or psychoanalysis.

All of the foregoing is consistent with the Pavlovian notion of "correct" thought leading to "correct" processing by the mind's second signal system, which in turn leads to "correct" behavior. It is basic in the thinking of the new China that change and improvement are almost always possible, given enough effort and the right kind of mutual help. Freud's concept of the unconscious, a part of the mind hidden from and inaccessible to direct confrontation and change but still able to influence behavior, is not compatible with the Chinese view. Moreover, Freudian psychology is seen as based on Western idealism, a philosophy with which the dialectical materialism of Communism is in opposition. Freud emphasized the individual, the self, and this finds little harmony in the Chinese state, which emphasizes the group, the nation, and the family. A thorough understanding of Freudian psychology requires years of study and practice, tending to create an elite group of doctors, and elite groups are anathema in the People's Republic. Finally, the subject of sexual drive is simply not felt to be important in the etiology of mental illness.

It is important that Freudian-trained readers consider these differences in opinion and interpretation when trying to follow the Chinese points of view and practice. They explain the laughter that followed the Sidels' question about Freud's influence in Chinese psychiatry (21). When we asked if Chinese psychiatrists believed in the developmental theory of mental illness, our Nanking hosts said flatly that they did not. "Under Chairman Mao's guidance, after Liberation [1949], everyone believes in dialectical materialism and everyone is happy. There is no conflict for the children." In response to the same question, Shanghai psychiatrists answered,

> We have not yet arrived at a unified explanation as to the causes of [mental] disease. Some people hold that the role is played by chemical changes in the brain or genetic factors. We think that a reasonable social system will reduce the environmental causes of mental diseases. But will it also be effective in reducing the occurrence of schizophrenia? Well, there are still some disputes.

One 1957 statistic cited for the prevalence of schizophrenia in the People's Republic puts it at one-tenth of Western countries (12).

The place that neurosis currently holds in Chinese psychiatric theory is especially hard for Western observers to discern, for although Freudian views are rejected, some similar terms with perhaps different connotations are maintained. Diagnoses of neurotic patients include such terms as neurasthenia, hysteria, phobia, and obsessive-compulsive neurosis. The most prevalent diagnosis is neurasthenia, a nonspecific term without an English equivalent. Common symptoms of neurasthenia are insomnia, headache, dreams, and pains (9). It is difficult to find detailed descriptions of the other diagnostic categories as the Chinese use them.

PSYCHIATRY IN NANKING AND SHANGHAI

Diagnosis

Our interviews with psychiatrists in Nanking and Shanghai confirmed much of the material already discussed and added some new information. In Nanking, hospitalized patients were classified as having schizophrenia, manic-depressive psychosis, involutional psychosis, organic psychosis, symptomatic psychosis (after Mayer-Gross, Slater, and Roth's definition [25], which includes various organic diseases that present with psychosis), and psychogenic psychosis, which includes hysterical psychosis and depression. Diagnostic categories for nonpsychotic disorders included neurasthenia, obsessive-compulsive neurosis, hysteria, and phobia. No detailed statistics were available for the frequency of these diagnoses in the neuropsychiatric hospital in Nanking, but schizophrenia was diagnosed in more than 50 percent of the patients. In Shanghai, additional diagnostic classifications of hospitalized patients included postpartum psychosis, encephalitis, senile psychosis, cerebral atherosclerosis, and mental disturbances secondary to stroke. According to psychiatrists with whom we spoke, about 60 percent of the patients at the Shanghai Psychiatric Institute are diagnosed as schizophrenic, with the remaining 40 percent given various other diagnoses.

No classification for childhood mental illness was given in Nanking, but one 10-year-old girl with "childhood schizophrenia" was seen at the Shanghai Psychiatric Institute. The only child in the hospital at the time, she was being treated on a ward for women. There has been a general lack of demand for psychiatric facilities for children in China, and there does not appear to be a subspecialty of child psychiatry. A unit for the treatment of children under 13 or 14 years of age was in operation at the Shanghai Psychiatric Institute prior to 1966, but it was closed after the Cultural Revolution because it was relatively unused. One or two of the hospital psychiatrists with the most experience in treating children were called upon when the need arose.

Personality disorder was recognized as a diagnostic entity, but the cases were said to be few and the patients were not usually treated in a mental hospital. In Shanghai this was felt to be a job for "reeducation" and was done at some other, unspecified, place. Personality disorder accompanying schizophrenia or epilepsy was treated by the hospital staff. A nonpsychiatric physician commented that in the early years after 1949, sedatives and "some treatment" of an undefined sort were given to homosexuals who suffered from anxiety, but that not many such patients had been seen in recent years. One reason suggested for this decline was that it might be due to the change in the social system and the radical change in the moral standards of the society.

Treatment

The average length of stay at the neuropsychiatric hospital in Nanking was three to four months. The figure given at the Shanghai Psychiatric Institute was 70 days, the same as quoted in earlier reports (14, 21).

Schizophrenia was treated with drugs, herbs, electroacupuncture, and regular acupuncture in both cities. The use of ECT and insulin coma therapy in Nanking has already been described, along with the use of medications for depression. Insulin coma therapy and ECT have not been used at the Shanghai Psychiatric Institute since 1970. The combined use of Chinese and Western modes of therapy was emphasized. Psychiatrists had the clinical impression that the dosage of Western drugs needed to bring about recovery was reduced by half when acupuncture and/or herbs were used concurrently.

Maximum dosages of medications for hospitalized patients in Nanking were as follows: chlorpromazine, 450 mg a day; trifluoperazine, 20 to 30 mg a day; perphenazine, 30 mg a day; and chlorprothixene, 450 mg a day. The following were the maximum daily dosages given to outpatients: chlorpromazine, 100 to 150 mg a day; trifluoperazine, 10 mg a day; perphenazine, 6 to 10 mg a day; and chlorprothixene, 100 to 150 mg a day. Imipramine for depressed patients was given in a dosage of 150 to 300 mg a day for two to four weeks and then discontinued if there was no improvement. In Shanghai the maximum daily dosage of chlorpromazine for inpatients was 600 to 700 mg when used alone and about 300 mg when combined with acupuncture and herbs.

We saw a variety of therapies at the Shanghai Psychiatric Institute. Group meetings of patients and staff seemed to be held regularly. A type of day care center in the form of a large recreation room was available for use by any patients who wished to go there. Carnival-style games, music, dance performances, and songs were held daily, with the patients themselves as the participants on stage and in the audience. Ping-pong and chess were played on the wards. Work was a regular activity. Jobs consisted of simple manual tasks: some patients wove small items, some put small paper fillers into toothpaste caps, and others worked in the hospital garden or helped with grounds maintenance. Articles made in the hospital were sold to factories, and proceeds went to buy recreational materials, books, ink, etc., for the patients' use.

Neuropsychiatric patients in Nanking were given "dis-

charge papers" upon their release from the hospital. These papers contained a list of medications, dosages, and the time and place of follow-up visits. Patients would usually return to the hospital to keep appointments. A different group of doctors and nurses from those who treated inpatients saw the patients in the outpatient department. The same therapist saw the patient on each visit, since the relationship between the therapist and the patient was felt to be important. Acupuncture was not given to discharged hospital patients in the outpatient department, in contrast to its use in the treatment of neurosis in various outpatient settings. Most relapses occurred within two years, and patients were advised to take their medications for at least that long after discharge.

At the Shanghai Psychiatric Institute, discharged patients returned to the hospital after two weeks to see the same doctor who had treated them on the ward. More visits could be scheduled as necessary. The doctor could help the patient in his readjustment at home and at work and would sometimes make visits to the factory or neighborhood on the patient's behalf. There was no social worker on the staff. Nurses worked with doctors in the outpatient department, but their role was not clarified. Unlike doctors, the nurses did not seem to alternate between the inpatient and outpatient departments.

Outpatient Care

Some mental health clinics in the cities were operated away from the hospital grounds, but little is known about them. An administrator of a local hospital in Shanghai informed us,

> Only an occasional mental patient is treated here [at this neighborhood hospital], and only on a temporary basis. Most of the follow-up is done in the district mental "prevention" clinics, which are open two to three days per week. These do outpatient follow-up and are staffed by the doctors and nurses from the mental hospital. The patients discharged from the mental hospital are given "trial discharges" and they return weekly for follow-up. They may be seen in the local hospitals like this one only for medicines or occasionally for emergencies. Those who need the closest outpatient supervision are given aftercare at the mental hospital instead of the district clinics.

In Nanking, neurotic outpatients were treated with sedatives, acupuncture, or other traditional techniques. There were no data on the number of neurotic patients, but they were said to be "very few." The diagnostic category of neurosis was broad and included symptoms like headache and "nerve pain." In general medical clinics, patients who were recognized as having no organic basis for their symptoms could be treated by internists or neurologists without requests for psychiatric referral. A physician in a general hospital in Peking stated, "Internists and other doctors treat neurotics in regular hospitals. They are treated with drugs and acupuncture. They are not admitted to the psychiatric hospitals." Bromides seemed to be commonly prescribed for nonspecific ailments. Phenobarbital was used frequently in factory and neighborhood health stations. A factory doctor and one of our guides each mentioned that they took small doses of perphenazine as often as several times a week to relieve tension.

Consultations were held between nonpsychiatric hospital personnel and staff from the mental hospital in Nanking. The consultations were reciprocal and seemed to be strictly case oriented.

Rehabilitation

The Chinese social structure appears to be very supportive of the mentally ill. Cooperation and the dignity of each citizen as part of the group are emphasized. The duties of the psychiatrist seem oriented toward enabling the patient to regain his position in his family and job. The whole matter appears capable of careful planning and execution from the time of the patient's original referral to a mental hospital to his reintegration in the community. Two case histories related by a physician at the Shanghai Psychiatric Institute illustrate this point.

> After a patient left our hospital and went back to his working unit, the authorities of that unit, in consideration of his health, shifted him to another workshop to do another kind of job. However, he took this in the wrong way. He thought that the administrator of this work unit might have some kind of prejudice against him, and he became very disappointed and returned to the hospital to ask the doctor's help. The doctor went to the working unit to learn about the whole process and to explain to the patient. The man gradually understood why his work was shifted, his disappointment disappeared, and he worked very well and was very pleasant.
>
> In another instance a patient had been a shop assistant in a department store. When he recovered and returned to his store, his leaders failed to understand him very well, and he was assigned to his original job. However, he was unable to adapt to the original job because the medicine interfered with his memory. Thus, he could not do accounts very well. When he came back to the hospital to ask for the doctor's help, the doctor went to this store and got the leaders to shift the patient's work. He became a warehouse keeper for a half year. His memory then recovered and he asked to do the same job he had held before.

Mobile Teams

One-third of the staff at the Shanghai Psychiatric Institute toured the surrounding countryside in mobile teams. This practice is common in all types of hospitals, general and specialized, and it represents an attempt to bring care closer to the people. The mental hospital teams consisted of three doctors and seven nurses. The whole staff took turns on mobile teams. An important duty of these groups was to train "barefoot doctors" in the management of acute psychiatric problems. Often the barefoot doctors could not immediately send psychiatric patients to the mental hospital, and they thus had to learn about drug and acupuncture treatment for such situations. One doctor reported, "The mobile team of the mental hospital came to our hospital a year ago. They gave two days of lectures at the hospital and worked in the clinics one week more to take measurements on rates of mental diseases."

It is apparent that much of the theory and practice of Chinese psychiatry is based on hospital practice. Almost all patients are sent to the hospital for treatment; follow-up care and community support for discharged patients is organized from the hospital. The hospital staff runs the outpatient departments and the outlying clinics and supplies the mobile teams that disseminate information on psychiatry to neighborhood and commune medical units. Private practice does not exist, and clinical research and training is hospital based.

TRAINING

Chinese medical students now receive instruction in neurology and psychiatry during a two-week series of lectures and visits to neuropsychiatric hospitals in their second year of medical college. Since the Cultural Revolution, medical students have had a three-year curriculum. Prior to the Cultural Revolution they studied for five or six years and received two weeks of psychiatric training in their fourth year (13). At present, psychiatry is part of the course in internal medicine, and lectures seem to be given by internists or neurologists. The departments of psychiatry that had formerly been a regular feature of medical colleges (8, 13) were suspended during the Cultural Revolution and have not yet been reinstated. It is not known whether separate departments of psychiatry will be reestablished in medical colleges. The whole field of psychiatry may be continuing its Cultural Revolution even though many other medical specialties have reorganized.

After they graduate from medical school, most doctors may have no further exposure to training in psychiatry until they come into contact with a mobile team from a regional mental hospital. The only literature we found in bookstores that dealt with psychiatry for non-psychiatrists consisted of manuals written for barefoot doctors. Several of these included concise descriptions of common manifestations of epilepsy, psychoses, and neurasthenia. The use of phenothiazines, barbiturates, and bromides was covered briefly. The manuals provided a picture of symptoms and of routine treatment. A small section of a recent manual for barefoot doctors discussed mental illness in this fashion. The section also discussed the concept that some mental illnesses are a reaction to an unspecified underlying disorder, perhaps recalling the pre-1949 influence of Adolf Meyer (26).

Psychiatrists receive their training in the mental hospitals. Graduates from the medical colleges are assigned to work in mental hospitals, apparently in numbers planned to fit the country's projected need for psychiatrists. The basic course lasts from 6 to 12 months, according to sources in Nanking and Shanghai. Taipale and Taipale (12) reported that two or three years of training were required, but this difference may indicate that the period of formal training in psychiatry has been reduced from what it was in 1972. Another explanation may be that the shorter period refers to the organized system of lectures and that the longer period refers to the total time required before a resident is felt by his peers and supervisors to be capable of fully independent work.

At the Shanghai Psychiatric Institute the psychiatry residents learned through practice, supervision, readings, and seminars. One doctor at the institute reported, "When the residents first come here, their psychiatric knowledge is quite limited, so we give them training for one-half to one year. In this period of time experienced doctors will give them guidance. They will acquire knowledge mainly through practice. They are assigned some books and literature to read, and through practice they will gradually be capable of doing independent work." The reading assignments consisted of compilations prepared by the teaching staff; students who read English were also assigned selections from texts such as those by Mayer-Gross, Slater, and Roth (25), Henderson and Gillespie (27), and Noyes and Kolb (28). The lectures for residents included topics such as neurology, neuropathology, neurobiochemistry, and psychopharmacology. Psychologists from the university were invited to present lectures from time to time, but they did not practice in the mental hospitals. This has been the case for many years (13).

Some foreign journals available to psychiatrists included *The American Journal of Psychiatry, Archives of General Psychiatry, Journal of Nervous and Mental Disease, British Journal of Psychiatry,* and *Acta Psychiatrica Scandinavica.*

Research efforts were directed toward examination of the effectiveness of therapy. A popular research topic seemed to be a search for the effects of combining Western and traditional Chinese methods of treatment. Chinese psychiatrists seemed uniformly interested in the current trends of basic laboratory research in the United States.

CONCLUSIONS

We have attempted to trace some developments in the history of psychiatry in China and to present a picture of the practice of and education in psychiatry as it has been applied in the People's Republic of China. The Chinese approach has had to deal with several large problems. One of these has been the need to expand services to meet the needs of the vast population. This has been approached by increasing the numbers of psychiatrists and mental hospitals to accommodate the severely mentally ill. Personnel and facilities had not existed in adequate numbers before 1949. Outpatient clinics have been developed, but little is known about them. The existing social structure has been used to advantage to help in the rehabilitation of discharged patients. Available psychiatric doctors and nurses are being used to train other medical practitioners in basic concepts and methods so as to increase the availability of care.

Another problem has been to develop a consistent theoretical approach to psychiatry, a difficulty not peculiar to the People's Republic of China. The special approach adopted by the Chinese emphasizes sociopolitical factors

whenever possible in theoretical formulations about psychiatry. Research has been pursued mainly in clinical studies, but these could be of great significance when published if they support the claim of decreased prevalence and incidence of almost all kinds of functional mental illness in the People's Republic.

Clearly, the available information about psychiatric practice in the People's Republic of China gives only a hint of the differences between our two systems. There has only been a preliminary and incomplete exchange of information to date, by travelers who cannot fully represent so complex a subject after relatively brief exposures. As West and East observe each other in the future, more exchanges and greater depth of contact may be expected to stimulate greater mutual interest and benefits.

Mental Changes Associated with Hyperparathyroidism

BY JOHN W. GATEWOOD, M.D., CLAUDE H. ORGAN, JR., M.D., AND BEVERLEY T. MEAD, M.D.

To document the point that hyperparathyroidism should be considered a possible cause of unexplained neurological and psychiatric symptoms, the authors present five case reports of confirmed primary hyperparathyroidism in which the patients initially appeared with problems that seemed mainly psychiatric. The presenting symptoms in these cases consisted of varying degrees of depression, catatonia, confusion, disorientation, fatigue, and lethargy; there was no associated bone or renal pathology in four of the cases. The authors include a review of the pertinent literature and a discussion of the effect of calcium and magnesium bivalent ions on the central nervous system associated with hyperparathyroidism. They conclude that more investigation of the role of magnesium in this disease seems warranted.

HYPERPARATHYROIDISM has been difficult to diagnose because it presents with such a wide variety of clinical symptoms (1, 2). It is a relatively "new" disease, and its clinical and hormonal dynamics are yet to be well understood (3), but fortunately it is now being recognized more frequently and earlier in its course. In this regard we feel that the widespread use of the 12-channel autoanalyzer (SMA-12) has been very important in creating a greater appreciation of hyperparathyroidism by bringing more incidental reports of hypercalcemia to the attention of physicians. It is also most fortunate that the laboratory finding of hypercalcemia is so consistent for this disorder because the clinical manifestations of hyperparathyroidism can be present in many different target organs of the body and give the clinician many surprises (4).

This paper gives particular attention to examples of hyperparathyroidism that presented only or chiefly with psychiatric symptoms. Also included is a discussion of the associated biochemical mechanisms that may create such symptoms.

CASE REPORTS

Case 1. Mr. A, a 63-year-old farmer, was initially admitted to the hospital for a cholecystectomy in July 1970. Ten days after what was considered to be a routine operation he became confused. It was initially suspected that he had developed postoperative hepatic failure; this was not confirmed by further investigation. He subsequently developed a thrombophlebitis of the right leg that was treated with anticoagulants and a broad-spectrum antibiotic.

Despite the improvement of his thrombophlebitis, the patient still showed signs of persistent confusion and occasional disorientation 15 days after the operation. His general physical condition had improved, however, and he was discharged from the hospital.

His confusion became even worse while he was at home; he was readmitted to the hospital four days after being discharged. Medical consultation was again obtained and a serum calcium determination of 11.9 mg/100 ml was noted, along with a serum phosphorus level of 1.0 mg/100 ml. Repeated determinations confirmed these findings and a diagnosis of primary hyperparathyroidism was made. A bone survey that included the teeth, phalanges, tibia, femur, radius, and skull revealed no radiographic changes compatible with hyperparathyroidism (see table 1).

On October 5, 1970, the patient was operated on. At this time a parathyroid adenoma measuring 1.5 cm by 2.5 cm was found near the inferior pole of the left lobe of the thyroid. The surgical pathology report identified it as a chief-cell adenoma.

This patient experienced a dramatic return to normal mental status within two weeks after removal of the adenoma. By that time he showed no mental confusion or other residual psychiatric symptoms. Since his discharge from the hospital he has gained 47 pounds.

The role of operative or postoperative stress as a pertinent factor in precipitating the symptoms of hypercalcemia is, of course, speculative. No evidence of bone or renal disease was found in this patient. Serum magnesium levels were not obtained.

Case 2. Rev. Mr. B, a 65-year-old clergyman, was admitted to the hospital in February 1967 with a 14-month history of progressive depression, constipation, fatigue, lethargy, and complaints of being "mentally dull." These symptoms, which had come on insidiously, were accompanied by occasional episodes of confusion, a 28-pound weight loss shortly before admission, and some incoordination of gross and fine movements of the hands.

The patient had had a resection of an adenocarcinoma of the soft palate three months before this admission, a duodenal diverticulectomy and appendectomy one year prior to admission, and a subtotal thyroidectomy for a benign thyroid adenoma 10 years previously. He had been under continuing psychiatric care for what was diagnosed as severe reactive depression just before the 1967 admission.

On admission, this patient's serum calcium determinations ranged from 15.7 mg/100 ml to 18.3 mg/100 ml. Serum phosphorus levels ranged from 3.5 mg/100 ml to 3.7 mg/100 ml. (Additional laboratory determinations are shown in table 1.) On the left side of the patient's neck, a palpable mass measuring

The authors are all with Creighton University School of Medicine, 10th and Castelar, Omaha, Neb. 68108. Dr. Gatewood is Clinical Professor and Dr. Organ is Professor and Chairman, Department of Surgery, and Dr. Mead is Professor and Chairman, Department of Psychiatry and Neurology. Address reprint requests to Dr. Organ.

TABLE 1
Clinical Measurements for Five Patients with Hyperparathyroidism

Clinical Measurement	Mr. A	Rev. Mr. B	Ms. C	Ms. D	Ms. E
Serum calcium	11.9 mg/100 ml	18.3 mg/100 ml	12.0 mg/100 ml	11.2 mg/100 ml	12.2 mg/100 ml
Serum phosphorus	1.0 mg/100 ml	3.5 mg/100 ml	2.4 mg/100 ml	2.6 mg/100 ml	2.5 mg/100 ml
Serum alkaline phosphatase	16 K-A units	10.8 K-A units	2.5 K-A units	24 K-A units	16 K-A units
Tubular reabsorption of phosphate	91.4 percent	80.6 percent	94.2 percent	—	—
24-hour urinary calcium excretion	179 mg/100 ml	523 mg/100 ml	320 mg/100 ml	410 mg/100 ml	—
Serum creatinine	1.35 mg/100 ml	5.4 mg/100 ml	1.2 mg/100 ml	0.8 mg/100 ml	1.0 mg/100 ml
Creatinine clearance	162 ml/minute	—	—	—	—
Serum electolytes	normal	normal	normal	—	normal
Blood urea nitrogen	16.8 mg/100 ml	60.5 mg/100 ml	11.0 mg/100 ml	14.2 mg/100 ml	20.0 mg/100 ml
I-131 uptake	—	9.4 percent	—	—	—
Bone survey	negative	positive	negative	negative	negative
Side of gland adenoma located	left	left	right	right	left
Type of adenoma	chief cell	chief cell	chief cell (mixed)	chief cell	chief cell

4.5 cm by 2.5 cm was noted. This mass was movable, smooth, well circumscribed, and nontender.

X rays of the skull showed a "salt and pepper" appearance suggestive of hyperparathyroidism. X rays of the hands demonstrated subcortical resorption of the phalanges, and X rays of the teeth showed absence of the lamina dura. Both of these are suggestive of hyperparathyroidism.

He was taken to the operating room on February 27, 1967. At this time a large parathyroid adenoma was removed near the inferior pole of the left lobe of the thyroid. The surgical pathology report described it as a chief-cell adenoma.

The patient showed remarkable improvement in his psychiatric symptoms; just three weeks after surgery he was considered to be mentally and emotionally "his old self." He has continued to be free of any mental symptoms, has regained most of the weight he had lost, and has returned to full-time activity in his profession.

Of particular interest is the fact that this patient experienced a recurrence of neuropsychiatric signs and symptoms at a time when he had become profoundly hypocalcemic. These symptoms were treated by intravenous calcium therapy. However, with a return to eucalcemic levels, the symptoms were not significantly improved until magnesium sulfate was added to the therapeutic regimen.

Case 3. In July 1970, Ms. C, a 56-year-old housewife, was transferred from the psychiatric ward of another hospital where she had been treated for catatonic schizophrenia for four months. A newly assigned medical student who was in the process of reevaluating the case for his staff physician ordered a serum calcium test that reported a level of 12.0 mg/100 ml.

Further studies and additional serum calcium determinations ranged from 11.8 mg/100 ml to 12.6 mg/100 ml, serum phosphorus levels varied from 2.4 mg/100 ml to 2.6 mg/100 ml, and the serum alkaline phosphatase was 2.5 K-A units. All other laboratory data, including serum electrolytes, protein electrophoresis, the cortisone suppression test, tubular reabsorption of phosphate (TRP), phosphate deprivation tests, and calcium infusion and calcium urinary excretion tests, were within normal limits (see table 1). An extensive radiographic bone survey also demonstrated no abnormal findings, and intravenous pyelography and renal function studies were within normal limits.

On July 18, 1970, a parathyroid adenoma was removed near the inferior pole of the right lobe of this patient's thyroid measuring 3.0 cm by 2.0 cm. The surgical pathology report described this as a mixed-type parathyroid adenoma with a chief-cell component. By the third day after the operation, Ms. C's serum calcium had dropped to 7.8 mg/100 ml; it returned to a normal range 13 days after surgery.

It should be noted that exhaustive screening procedures had not revealed any evidence of bone or renal disease in this patient. Although the diagnosis was made mainly by serendipity, the patient has made a gradual recovery from her psychiatric illness. The attending psychiatrist feels her progress has been exceptionally good and attributes this to the parathyroidectomy. She has not been given any medication for her mental illness since the surgery.

Case 4. Ms. D, a 74-year-old housewife, was admitted to the psychiatric service of the hospital in May 1971 with a diagnosis of involutional depression. In the course of her evaluation it was noted that she had an elevation of her serum calcium to 11.2 mg/100 ml and a serum phosphorus depression to 2.6 mg/100 ml. These abnormal findings were confirmed by repeated determinations (see table 1).

A radiographic bone survey revealed some osteoarthritic changes in the interphalangeal joints but did not demonstrate any findings suggestive of hyperparathyroidism. Chest X ray revealed a calcified granuloma in the right mid-lung field but no other abnormalities. An intravenous pyelography showed only a mild ptosis of the right kidney. X rays of the teeth showed some cavity formation and alveolar recession but no absence of the lamina dura. An I-131 uptake at 24 hours was 8.7 percent, which is considered to be in the hypothyroid range.

On June 8, 1971, a parathyroid adenoma near the inferior pole of the right lobe of the thyroid was excised. The surgical pathology report described it as a chief-cell adenoma. The patient had a remarkably easy postoperative recovery. Her depression disappeared without the use of antidepressant medication and her psychiatrist confirmed that she continued to do very well three years after surgery.

It should be noted that the value of the SMA-12 as a routine screening instrument is well demonstrated in this case. It might very well be a part of the routine evaluation of patients in mental institutions. The rapidity with which the diagnosis was determined in case 4 was directly related to the early recognition of the presence of hypercalcemia. Unfortunately, no magnesium levels were obtained on this patient to correlate with her changing symptomatology.

Case 5. Ms. E, a 75-year-old housewife, was admitted to the neurology service of the hospital in May 1972 for the investigation and treatment of a suspected cerebral vascular accident. She was a known diabetic, adult-onset type, and had been hypertensive. She also had a history of recent syncope, progressive confusion, and drowsiness.

An SMA-12 blood chemistry profile indicated that she had an elevated serum calcium of 12.6 mg/100 ml and a decreased phosphorus level of 2.4 mg/100 ml. On subsequent determinations serum calcium was 12.2 mg/100 ml and serum phosphorus was 2.5 mg/100 ml (see table 1). A radiographic bone survey and serum alkaline phosphatase test were within normal limits.

On May 20, 1972, a parathyroid adenoma was removed near the inferior pole of the left lobe of this patient's thyroid gland. The surgical pathology report described it as a chief-cell adenoma.

Ms. E had an uneventful surgical recovery and, according to the referring physician, experienced a remarkable improvement in her neuropsychiatric condition. She is currently receiving no medications, her diabetes is well controlled, and she remains normotensive.

The blood chemistry SMA-12 profile obtained on admission was very valuable in alerting the attending neurologist to the possibility of a parathyroid adenoma in this case.

DISCUSSION

Literature Survey

In the literature on hyperparathyroidism, comparatively little attention has been given to the psychiatric symptoms often associated with it. The mechanism by which these symptoms are produced remains unknown. They are believed to be related in some way to the associated hypercalcemia, but other factors may be involved as well.

The psychiatric symptoms most commonly described are those associated with an acute brain syndrome or general depression of mental function. Soon after parathyroid hormone was isolated, Collip (5) reported an apparent psychic depression in test animals receiving parathyroid hormone. Boyd and associates (6) described a case of hyperparathyroidism with associated symptoms of "marked lassitude of the body and mind." After their patient's parathyroid adenoma was removed, mental alertness returned. Investigating this and other reports, Hannon and associates (7) discovered that twice the amount of electrical current was required to excite an isolated nerve in a patient with hyperparathyroidism.

Over the next few years, several clinical cases were reported showing "mental retardation," "listlessness," "apathy," and "disorientation" (8–13). Harmon (13) also noted two unusual findings in a case of hyperparathyroidism in a six-year-old child—permanent neurological damage and a serum magnesium deficit. Eitinger (14) reported evidence of mental symptoms in 7 of 50 descriptions of primary hyperparathyroidism in 1942. He presumed these were related to hypercalcemia. Chaplin and associates (15), reporting on vitamin D intoxication, referred to a "mild psychosis" in patients with elevated serum calcium.

Among the more recent reports, Karpati and Frame (16) presented the first review of neuropsychiatric disorders in hyperparathyroidism. They wrote:

> It is surprising that neuromuscular signs and symptoms are not more often reported in patients with hyperparathyroidism in view of the characteristic disturbances of calcium homeostasis and the prominent role of this bivalent ion in the electrobiology of nervous and muscle tissue. (16)

They also noted either psychiatric or neuromuscular findings in 14 of 23 cases of hyperparathyroidism. Improvement in mental symptoms followed surgery, although 3 patients in the series had acute psychotic episodes three to four days following surgery but then recovered rapidly and without residual symptoms. (In many respects these cases resemble our case 2.)

Potts and Roberts (17) also described two cases in which removal of a parathyroid adenoma was followed by confusion and psychotic behavior. Bergeron and associates (18) observed the same phenomenon and noted that serum magnesium levels were depressed, and in some cases the abnormal mental behavior improved after the administration of magnesium (note our case 2).

Various reports in recent years (19–24) tend to repeat the findings described previously, but a few of these cases reported symptoms that are not typical of the usual acute brain syndromes, such as delusions and aggressive behavior. Some of these cases were complicated by the preexistence of other physical diseases or mental disorders (as may be true in our case 3, who presented with schizophrenic symptoms, and case 4, who showed the apparent symptoms of involutional depression).

Possible Causes

In all of the reports on hyperparathyroidism in which some mention of mental symptoms has been included, no explanation has been offered for their cause except for the general dampening effect that hypercalcemia seems to have on any neurological function. Although an unproved cause, this does seem to be a reasonable assumption, even though the exact means by which calcium ions have this dampening effect is not understood. The effect of metallic ions on the functioning of the nervous system, and indirectly on human behavior, has received additional interest recently because of the use of lithium therapy for manic states. Since lithium has a dampening effect similar to that of calcium ions, it is intriguing to

consider what possible value calcium salts might have if used to amplify or substitute for lithium action.

Another metallic ion effect that may be significant in hyperparathyroidism is the influence of magnesium. Because of magnesium's metabolic interrelationship with calcium, the neurologic sequelae of depletion of body magnesium is certainly a mechanism deserving further consideration. Magnesium deficiency has been demonstrated to occur in hyperparathyroidism. This could be as important a causal factor as increased calcium.

In humans, magnesium deficiency is characterized by neuromuscular irritability and convulsions as well as confusional states and mental depression. Both calcium and magnesium in higher concentrations tend to depress the excitability of the myoneural junction, whereas high magnesium concentrations have a definite central depressive effect ("magnesium narcosis") that can be reversed by the administration of calcium (25).

During the hyperparathyroid state there is a negative magnesium balance, with increased urinary excretion of magnesium and a variable serum magnesium level. This is due in part to the mobilization of magnesium along with calcium from bone. If magnesium is cleared through the kidneys more rapidly than calcium, increased levels of urinary magnesium without elevated serum magnesium can result.

Removal of the cause of the hyperparathyroid state creates a positive magnesium balance and retention of magnesium intracellular components accompanied by a decrease in serum and urinary magnesium. A closer study of magnesium intra- and extracellular alterations in hyperparathyroidism certainly is warranted. These alterations may prove to be very significant in both the preoperative and postoperative mental disorders in hyperparathyroidism.

The Effect of Living Alone on Bereavement Symptoms

BY PAULA J. CLAYTON, M.D.

The author reports on a study of widows and widowers who were followed for one year after the deaths of their spouses. The study shows that bereavement itself rather than the effects of living alone influences the occurrence of depressive symptoms in widows and widowers at one month. The data gathered also support the idea that younger people who have lost a spouse tend to show more physical depressive symptoms and to require hospitalization more often than either matched married controls or older widows and widowers at one year.

MY COLLEAGUES AND I have investigated social isolation as a cause of bereavement symptoms as part of a prospective study of widowhood. In previous reports (1, 2), we noted a high prevalence of physical and psychological symptoms of depression in the first year of widowhood. Similar symptoms have been reported in other prospective and retrospective studies of widowhood, beginning with Freud (3) and continuing with Lindemann (4), Marris (5), Maddison and Viola (6), Yamamoto and associates (7), Parkes (8), Kennell and associates (9), and Heyman and Gianturco (10).

Using specific diagnostic criteria for depression, we have shown that, in addition to individual psychological and somatic symptoms of depression, 35 percent of our sample of widows and widowers had a depressive syndrome one month after their bereavement (11) and 17 percent had this same syndrome one year later (12). Forty-six percent of the sample experienced this cluster of depressive symptoms at some time during the first year of bereavement and 13 percent had the syndrome for the entire year (13).

The question arises of whether these symptoms are due to the bereavement itself or to the loneliness and social isolation that result from the bereavement. To answer this question, we divided our widows and widowers into those who lived alone and those who lived with someone (children, siblings, or parents) after the bereavement. We then compared the two groups on many variables, including the presence of depressive symptoms, one month after bereavement and again at one year.

We also followed a group of age-matched, married controls longitudinally and compared the prevalence of depressive symptoms over a one-year period in the four groups—the widows and widowers who had lived alone were compared with their controls, and those who had not lived alone were compared with their controls.

METHOD

The method of this study has been described fully elsewhere (1, 2, 11, 12). From the death certificates of the city and county of St. Louis we chose names of men and women who had recently been widowed. A table of random numbers was used to select subjects for interview. We saw 109 people who had been widowed for no longer than one month. These included 76 women and 33 men whose average age was 61. We saw these people in their homes for approximately two hours, using a systematized and open-ended interview.

Shortly after we selected our study population, we matched them through the voter registry with married people of the same age and sex and from the same voting district, preferably from the same street. We interviewed the bereaved again at four months. At one year we interviewed the bereaved and their married controls. We were particularly interested in mortality in the widows and widowers and morbidity as measured by presence of depressive symptoms, physician visits, drug use, and hospitalizations during the previous year.

The criteria for diagnosis of depression in this study are those recommended by Feighner and associates (14). The criteria were feeling depressed or feeling lost or numb plus four of the following eight symptoms: anorexia or weight loss; sleep disturbance, including hypersomnia; fatigue; feeling restless; loss of interest; difficulty concentrating; feeling guilty; and wishing to be dead or thoughts of suicide. This cluster had to be present at the time of the interview for a diagnosis of depression to be made.

Statistical evaluation of the data presented in this report was accomplished by means of the chi-square test with Yates' correction and the t test for data requiring parametric evaluation. Both statistics were used as two-tailed tests. Differences were defined as significant when there was 1 or less than 1 chance in 20 that they had occurred by chance.

Read at a New Research session at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

RESULTS

One-Month Follow-Up

At one month we examined symptoms in 108 widows and widowers. One man in the original sample was in a nursing home and had a chronic brain syndrome; it was felt for this particular evaluation it was best to exclude him. Sixty-one (56 percent) of the 108 people were living alone at one month and 47 (44 percent) were not living alone. Forty were living with children, 4 with siblings, and 3 with parents. The average age of those living alone was 65; for those not living alone it was 58 ($p<.01$). This difference is due to the fact that almost all of the younger people in the study (particularly the women) had young children and were therefore not considered to be living alone.

There were approximately equal percentages of women in both groups: 67 percent of those living alone were women and 74 percent of those not living alone were women. There were no differences in the two groups in socioeconomic status, length of illness of the deceased, or assessment of the marriage before the illness as good or poor. Depressed mood, sleep disturbance, crying, anorexia, weight loss, difficulty concentrating, poor memory, loss of interest, fatigue, diurnal variation, feelings of worthlessness, feeling that one is a burden, feeling guilty, feeling hopeless, wishing one were dead, and suicidal thoughts all occurred with equal frequency in both groups.

Equal numbers of both groups lost a small or large amount of weight in the first month after bereavement; more of those living alone gained weight (12 percent versus 2 percent). Restlessness occurred in 63 percent of those living alone and 24 percent of those not living alone ($p<.05$). Irritability occurred in 8 percent of those living alone and 26 percent of those who were not living alone ($p<.05$).

Considering the number of variables we examined, it would be difficult to say that these differences did not occur by chance alone. Irritability has been associated in our previous studies with younger age. This is most likely due to the fact that younger people had someone against whom to direct their irritability (e.g., children).

Using the criteria for depression described above, 34 percent of those living alone and 36 percent of those not living alone were given a diagnosis of depression. Physical symptoms such as headaches, blurred vision, dyspnea, abdominal pains, constipation, attacks of anxiety, urinary frequency, dysmenorrhea, and other pains, especially joint and back pains, were inquired about. There were no differences in the occurrence of these symptoms in the two groups. There were also no differences in the use of hypnotics or tranquilizers or in visits to a physician. This means that those who were living alone did not necessarily go to their physician just because they had no one to talk to. Thus social isolation did not seem to influence the psychological symptoms, physical symptoms, or medical treatment of the widows and widowers during the first month after bereavement.

One-Year Follow-Up

Of the 47 widows and widowers who were not living alone one month after bereavement, 7 were living alone one year later. Most of these people had children who married or went into the service. Three people who had been living alone were no longer living alone at one year. In this population of 108 people, 9 percent changed their intimate living arrangements during the first year after bereavement.

At one year we followed up 94 people (86 percent of the original sample). Four of these people had died, leaving 90. The man in the original sample who was in a nursing home with a chronic brain syndrome was one of those who died. By one year one woman was in a nursing home and had a severe chronic brain syndrome; she was excluded from the calculations. At the one-month follow-up this woman had had a mild diagnosable chronic brain syndrome.

Our one-year data deal with 89 people. Fifty-two (58 percent) were living alone and 37 (42 percent) were not. Of those who were not living alone, 29 were living with children, 2 were living with siblings, 3 with their mother, 1 with a niece, 1 was a housemother, and 1 man had remarried. The average age of those living alone was 63, of those not living alone, 57 ($p<.05$).

Again there were no differences in the percentage of women in each group or in the socioeconomic status of the groups. Both groups reported with equal frequency previous separation, divorce, or unhappiness in the marriage from which they were widowed; these factors did not seem to influence whether or not they lived alone.

Table 1 shows the incidence of psychological and somatic symptoms of depression as well as the depressive syndrome in these groups at one year. The frequencies represent the presence of these symptoms. There was a tendency for those living alone to report depressed mood and sleep disturbance more often, but this trend did not achieve significance. Those living alone also felt more often ($p<.05$) they had nothing to look forward to and had a tendency to feel hopeless and to wish they were dead. Thus there is a slight indication that living alone produces more psychological distress a year after the bereavement. This is further emphasized by the finding that those who had a collection of depressive symptoms were mainly in the group living alone.

It was also found that equal numbers in both groups lost a small or large amount of weight or gained weight. Most of the widows and widowers also dreamed infrequently about the deceased spouse. Two-thirds of those living alone and one-half of those living with someone had "good" dreams.

Table 2 shows that those living alone had no more physical symptoms and received no more medical treatment, with the exception of the use of hypnotics, than those not living alone. The finding of the use of hypnotics lends credence to the previous statement that there is more distress in those living alone.

It was also found that 35 percent of those living alone related their visits to physicians to grieving while only 18

percent of those not living alone did so. The two groups had similar numbers of visits to physicians.

A large number of physical symptoms showed no differences between the two groups. These included the following: headaches, blurred vision, dyspnea, chest pains, palpitations, anxiety attacks, abdominal pains, vomiting, constipation, urinary frequency, dysmenorrhea, other pains (especially in the back and joints), dizziness, fainting, skin rashes, excessive sweating, and increased or decreased smoking.

Other variables compared included problems experienced since the death, advice sought about these problems as well as more general advice, financial support, spending habits, working habits, socializing, drinking habits, and changes in day-to-day habits such as cooking, cleaning, and taking care of personal appearance. No differences were found between groups on these variables.

We also found no differences between groups in feelings about the marriage, the illness, the death, the funeral, visiting the grave and specific thoughts about the deceased (e.g., thinking about him or her daily, sensing his or her presence, cultivating that presence, or avoiding reminders of the deceased).

No differences were found in feelings and actions regarding dating, sex, and remarriage. Twelve percent of those who were living alone reported having a severe reaction on the anniversary of their spouse's death; no one who was living with someone reported this reaction. A severe reaction was defined as a syndrome of more than one day's duration with a low mood described as "miserable" or its equivalent, excessive crying in places other than the church or grave, and/or work function interrupted. The difference was not significant, but it may be that one year after the bereavement living with someone attenuates this reaction as well as other symptoms.

Comparisons with Matched Controls

Table 3 shows depressive symptoms in those living alone and those not living alone and their matched married controls. The frequency of each symptom is not shown. Rather, the table shows whether the subjects and controls had had the symptom at any time during the year. There are marked differences between our subjects and their controls on a large number of depressive symptoms. Widowed subjects, living alone or not, could expect to experience a number of distressing psychological and somatic depressive symptoms in the first year compared with controls. No group reported suicidal thoughts with any great frequency.

Table 4 shows that there are differences in some physical symptoms (mainly in subjects not living alone—the younger group). However, a large number of other physical symptoms show no differences. General poor health was no different between subjects and controls.

Table 5 shows medical treatment for the subjects and their controls. Here the only difference that emerges is a difference in hospitalizations, which occur more often in subjects living with someone (the younger group), and in the use of hypnotics in subjects living alone.

DISCUSSION

The overwhelming evidence of this analysis indicates that the bereavement itself, rather than the effects of loneliness or social isolation, influences the occurrence of depressive symptoms as well as medical attention for symptoms one month after the loss of a spouse. The be-

reavement also influences the occurrence of symptoms over the period of a year. There is some indication from the data that the younger widows and widowers living with someone had more physical symptoms and more hospitalizations in the year after bereavement than their controls and the older widows and widowers. Parkes (8) and Maddison and Viola (6) have demonstrated that younger people show more physical symptoms in response to bereavement than older people. These findings support that idea.

It may be that those living alone experience more depressive symptoms and more depressive syndromes than those living with someone one year after bereavement. Thus with time those living with someone do better. Be-

The Validity and Significance of the Clinical Diagnosis of Hysteria (Briquet's Syndrome)

BY SAMUEL B. GUZE, M.D.

The author states that a valid diagnostic classification based on the medical model is a sine qua non for progress in psychiatric research and treatment and that such classification requires follow-up and family studies. To illustrate this point he reports on studies showing that hysteria, or Briquet's syndrome, is a valid clinical entity that follows a predictable course and clusters in certain families. He also reports that an association between hysteria and sociopathy has been demonstrated, suggesting that the two conditions may arise from similar etiologic and pathogenetic factors.

THE EFFORTS OF MY COLLEAGUES and me to study hysteria and related conditions derive from our views about psychiatric diagnosis. We believe that a valid diagnostic classification is a sine qua non for progress in understanding the nature and causes of psychiatric disorders and for developing effective treatments.

There was a time when many psychiatrists rejected the possibility, desirability, or necessity of valid diagnostic classification. They argued that such efforts to label patients were misleading and antihumanitarian. They argued that labeling a patient undermined therapeutic optimism and led to therapeutic failure. They never supplied data to support their assertions, but their views received widespread attention and respect.

Today, although few leaders in psychiatry openly champion this position, it has been adopted by many in the field and has found many nonpsychiatrist adherents. The latter are found chiefly among various so-called radical groups, including some social scientists, political activists, and a variety of social critics who are anti-establishment and antimedical. Their objection to diagnosis stems from a rejection of the medical model of psychiatric disorders. This rejection reflects a misunderstanding of the nature of this model and an unwillingness to accept any view of psychiatric disturbance that does not see it as a reaction to negative social, economic, and cultural forces in Western technological capitalist society.

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Dr. Guze is Professor of Psychiatry and Vice-Chancellor for Medical Affairs, Washington University School of Medicine, 4940 Audubon Ave., St. Louis, Mo. 63110.

This work was supported in part by grant AA-00209 from the Alcohol, Drug Abuse, and Mental Health Administration and by grant MH-19972 from the National Institute of Mental Health.

THE MEDICAL MODEL

As I have argued elsewhere (1, 2), the medical model requires no assumptions about etiology or effective treatment. It assumes only that there are different psychiatric disorders with different clinical pictures, natural histories, etiologies, and mechanisms and that different disorders will respond best to different treatments. This assumption results in efforts to divide psychiatric disorders into homogeneous groups based upon common etiology, pathogenesis, clinical features, and response to treatment. Features that patients have in common are the major focus of concern. Diagnosis is the medical term for this kind of classification. Its essential role is implicit in the medical model. Physicians have traditionally worked to recognize and characterize different illnesses and to distinguish one from another.

The causes of most psychiatric disorders are not known; they will become known only through research. Dogmatic assertions about etiology cannot be justified and cannot be considered adequate grounds for rejecting the medical model.

The medical model may be contrasted to its principal alternatives. The first alternative presupposes a general vulnerability to psychiatric disturbances in each individual, presumably as the result of early life experiences. The particular form of the disturbance is of secondary concern and is explained in terms of chance individual and environmental circumstances and in terms of the severity of the disturbance. Research into the nature of psychiatric disturbance and efforts at treatment are primarily directed at the hypothetical general vulnerability. The individual—his idiosyncratic circumstances, life history, and reactions—is the focus of concern.

The second principal alternative is based on the assumption that the social, economic, and political context of psychiatric disorders is of primary etiologic importance. Again, the form of the psychiatric condition is given little weight; diagnosis is minimized or ignored. Frequently—perhaps usually—the two alternative viewpoints are combined.

Although these descriptions are brief and incomplete, they indicate the thrust of the conflicting views. It is difficult to understand how experienced clinicians can fail to see that psychiatric disorders come in many different forms, that they are distinguishable from one another by more factors than simply their severity, and that classification or diagnosis is inevitable.

DIAGNOSTIC VALIDITY

What then is the best way to classify psychiatric disorders? I have elsewhere (1, 2) presented an approach that permits a "bootstrap operation," which offers hope for achieving, in time, a valid, generally accepted diagnostic classification.

Attempts to validate a clinical diagnosis should begin with a reasonably clear clinical description of the cases to be included within the particular category. One may start with a single striking manifestation or with a combination of manifestations, depending on previous clinical experience or intuition. Having defined the clinical category, the validity of the diagnostic grouping will depend upon demonstrating a common etiology, a similar pathogenesis (similar changes in anatomy, physiology, or chemistry), a uniform clinical course, and, in at least some disorders, an increased prevalence of the same illness in close relatives of index cases.

A completely validated category would require demonstrating all these points; such validation may be achieved only infrequently, as with certain specific gene-linked disorders such as sickle-cell anemia or phenylketonuria. For most clinical disorders, complete diagnostic validity has not been established and further reclassification is necessary.

The process of diagnostic validation is based on viewing clinical diagnosis as a prediction. Diagnosis should predict etiology, pathogenesis, clinical course, and familial illness patterns. A degree of diagnostic validity is established to the extent that it does predict these factors. For the common psychiatric disorders, too little is known about etiology or pathogenesis to validate diagnoses using these measurements. Tentative diagnostic validity must therefore depend upon clinical course and familial illness patterns.

Follow-Up Studies

The important question to be answered is, Do a significant number of patients with a particular diagnosis show the diagnostic features of another illness at follow-up? If they do, it would suggest that the original sample was not homogeneous and that the diagnostic criteria should be modified to correctly predict this differential outcome. Follow-up studies also contribute to diagnostic validity through analysis of prognosis. Marked differences in prognosis, such as between complete recovery and chronic persistent illness, suggest that the diagnostic group is not homogeneous and, again, that revision of diagnostic criteria may be indicated. A variable prognosis is not as logically compelling in indicating diagnostic heterogeneity as is a change in diagnosis; the same illness may have a varied outcome. Until more is known about the basic nature of psychiatric disturbances, however, gross differences in prognosis challenge the validity of a diagnosis.

If follow-up study indicates that few of the original cases appear with diagnostic features of another disorder, and if the prognosis of all of the cases has been generally similar, one may conclude that the original diagnostic grouping has been tentatively validated.

Family Studies

Family studies are important in investigating the etiology of illness. They are also important in the validation of diagnosis. An increased prevalence of the same disorder among close relatives of index cases suggests that one is dealing with a valid entity, independent of etiology. Since not all illnesses necessarily show familial segregation, the absence of an increased family prevalence cannot contribute to the question of diagnostic validity.

In summary, a psychiatric diagnosis may be considered tentatively valid if patients with a specific diagnosis do not show diagnostic features of a different illness at follow-up, if they have had a similar course, and if an increased prevalence of the same condition is encountered among close relatives. Thus the establishment of diagnostic validity requires follow-up and family studies.

DEFINITION OF TERMS

The application of these principles to the diagnosis of hysteria first requires attention to definitions. Two related terms are encountered frequently in the literature: "conversion symptom" (or conversion reaction) and "hysteria." The careless use of these terms may result in confusion. Most authors fail to indicate how they use these terms and do not make clear whether or not they regard them as equivalent. For some the terms refer to individual symptoms and for others to personality styles or symptom patterns. Patients described under these labels may include such diverse groups as young girls with sudden amnesia, middle-aged men with severe depression who complain of persistent abdominal pain, known epileptics with puzzling spells, patients with early disseminated sclerosis, and women with dystonic reactions to phenothiazines. No wonder there is some despair regarding the usefulness of psychiatric diagnosis!

The studies summarized below were based on differentiating between conversion symptom and hysteria. A gratifying degree of diagnostic validity is evident when conversion symptom and hysteria are used to refer to different phenomena.

Conversion Symptom

Conversion symptom refers, in a purely descriptive way, to an unexplained symptom suggesting neurological disease. Amnesia, unconsciousness, paralysis, spells, aphonia, urinary retention, difficulty in walking, anesthesia, and blindness are common and classic examples of the so-called pseudoneurological or grand hysterical symptoms. To call these symptoms unexplained means only that the history, neurological examination, and appropriate diagnostic tests have not uncovered a satisfactory explanation for them. The use of the term in this sense carries no etiologic or pathogenetic implications.

Although the term "conversion symptom" derives from the psychoanalytic theory of the unconscious conversion of psychic energy, its use should be restricted. Unexplained pains or other unexplained medical symptoms should be excluded from the category of conversion symptom to preserve greater specificity. If such unexplained medical symptoms as headaches, backaches, and abdominal pains were included, the term would come to mean nothing more than an unexplained medical symptom. Its differential diagnosis would include the whole range of medical disorders.

Hysteria

Hysteria, on the other hand, is used to refer to a syndrome first systematically described by Briquet in 1859 (3). It was recharacterized by Savill in 1909 (4) and by Purtell and associates in 1951 (5). These authors described a polysymptomatic disorder seen predominantly in females. It begins early in life, usually before the age of 20 and nearly always before the age of 30, and is characterized by recurrent or chronic ill health, the complicated history of which is frequently described dramatically.

Characteristic features of the clinical history, most of which are to be seen in all patients, include many and varied pains, anxiety symptoms, gastrointestinal disturbances, urinary symptoms, menstrual difficulties, sexual and marital maladjustment, nervousness, mood disturbances, and conversion symptoms. Frequent visits to physicians, the use of a large number of medications, excessive hospitalizations, and excessive surgery are also seen in the florid symptom picture. To avoid ambiguity and the pejorative implications associated with the term "hysteria," I have proposed calling this symptom complex Briquet's syndrome as an equivalent diagnosis that is free of prejudice and unburdened by historical conflicts (2).

I would like to emphasize the following point: conversion symptoms are individual symptoms while hysteria is a polysymptomatic disorder.

RESULTS OF INVESTIGATIONS

The following conclusions are derived from a series of interconnected follow-up and family studies from the Department of Psychiatry, Washington University School of Medicine, St. Louis, over the past 15 years.

Hysteria, or Briquet's syndrome, is a recognizable syndrome that is very similar from patient to patient and may be identified by standard clinical examination. It generally runs a prolonged course over many decades, although there may be fluctuations in intensity (6, 7).

Conversion symptoms, on the other hand, may be seen in a wide range of psychiatric, neurologic, and general medical disorders, including hysteria (2, 8). They may also be seen in patients who show no other evidence of illness (2). The course and prognosis of patients with conversion symptoms are variable, depending upon the underlying disorders (8). Hysteria and sociopathy[1] are two of the most common psychiatric disorders associated with conversion symptoms (8).

Hysteria runs in families. About 20 percent of first-degree female relatives may suffer from the same disorder; male relatives show an increased prevalence of sociopathy and alcoholism (9, 10).

An increased prevalence of hysteria is seen in the first-degree female relatives of male sociopaths; first-degree male relatives of men with sociopathy show an increased prevalence of sociopathy and alcoholism (11).

There appears to be a pattern of assortative mating between hysterical women and sociopathic men. Sociopathy is increased in husbands of hysterical women and hysteria is increased in the wives of sociopathic men (10, 12).

Sociopathy and hysteria are found in the same women more often than would be expected by chance (13). An early delinquent and antisocial history frequently precedes the manifestations of hysteria (13). Sociopathy in fathers appears to be particularly associated with the development of hysteria in delinquent and sociopathic girls (14).

Since hysteria is characteristically a disorder of women and is rarely seen in men, and since sociopathy is predominantly seen in men although it may occur in women, it has been suggested that, "depending upon the sex of the individual, the same etiologic and pathogenetic factors may lead to different, although sometimes overlapping clinical pictures" (13).

Recent work with hyperactive children, which was stimulated in part by the findings described above, may help clarify the development of both hysteria and sociopathy. Hyperactive children appear to carry an increased risk of delinquency and sociopathy (15). The results of two studies of the families of hyperactive children (16, 17) are of great interest here. Each of these studies found an increased prevalence of sociopathy in the fathers and of hysteria in the mothers of hyperactive children compared with parents of control children. Similar findings were not found in adoptive parents of hyperactive children (18).

A FORMULATION

Based upon these studies, the following formulation may be useful: Hysteria and sociopathy have a common familial origin, whether genetic, social, or both. The earliest manifestations of the adult disorders may take the form of the hyperactive child syndrome. As the child matures, various forms of delinquency and antisocial be-

[1]Sociopathy, or antisocial personality, is defined as a disorder beginning early in life (before the age of 15) and manifested by recurrent antisocial, delinquent, and criminal behavior, including school troubles (e.g., truancy, fighting with teachers, suspension, expulsion), excessive fighting in general, running away, periods of wanderlust, poor job record (e.g., fired, quit without other job available, no sustained job), poor marital record, poor military record, history of alcohol and/or drug abuse, and trouble with the police.

havior may become evident. The clinical picture in adolescence and adulthood will depend in part on the sex of the individual. Briquet's syndrome will predominate in females and the sociopathic constellation will predominate in males.

Although the importance of the family in the pathogenesis seems clear, how the familial origin leads to the specific clinical disorders is not known. The possible interactions among parent-child relationships, socioeconomic status, and neurobiological factors remain to be clarified. The significance of the hyperactive child syndrome is also still obscure. Its presence may indicate some difficulty in central nervous system development or maturation.

Finally, the evidence pointing to an association between sociopathy and hysteria indicates that the research methods used in the studies described above—complementary follow-up and family studies—can produce data useful in studying etiology as well as in validating diagnostic classifications.

Workshop on Writing for Scientific Journals

The 1975 annual meeting of the American Psychiatric Association will feature the second annual workshop on writing for scientific journals, to be held from 9 a.m. to 5 p.m. on Sunday, May 4 (the day before the annual meeting begins). The workshop, cosponsored by APA and the American Medical Writers Association (AMWA), will offer practical information and instruction on four subjects: common writing faults, organizing medical reports, getting your words on paper, and submitting a manuscript. Work assignments, which will be sent to registrants before the meeting, will form the basis for initial discussions during the workshop sessions. The course will begin with brief introductory lectures by the AMWA faculty, who include Charles G. Roland, M.D., chairman of the Department of Biomedical Communications, the Mayo Foundation; Barbara G. Cox, medical writer, Instructional Development Section, the Mayo Foundation; and Martha Tacker, Ph.D., free-lance medical writer and editor. Following the lectures there will be small-group discussions on the four basic subjects. The workshop will conclude with a panel discussion in which participants will have the opportunity to question the editors of several psychiatric journals.

Registration is limited to 40 participants. All applications for participation must be received by April 7; the registration fee is $65. For further information on registration write to Charles G. Roland, M.D., Department of Biomedical Communications, the Mayo Foundation, Rochester, Minn. 55901.

The Treatment of Adopted Versus Neglected Delinquent Children in the Court: A Problem of Reciprocal Attachment?

BY DOROTHY OTNOW LEWIS, M.D., DAVID BALLA, PH.D., MELVIN LEWIS, D.C.H., AND ROBERT GORE

The authors investigated the discrepant treatment by a juvenile court of adopted versus neglected delinquents. Adopted delinquents received harsher dispositions in spite of the fact that neglected delinquents often faced more serious charges. The two groups are compared in terms of family structure and the criminal and psychiatric histories of their parents; none of these seems to account for the adoptees' harsher treatment. The authors hypothesize that an interplay of late adoption, intrinsic vulnerabilities in the children, and weakness of parental bonds accounts for the differential outcomes.

THE PURPOSE OF this study was to investigate the apparently discrepant handling by the juvenile court of adopted versus neglected delinquent children and to explore several possible hypotheses that might account for this differential treatment.

Seven of the 262 children (2.5 percent) referred to a psychiatric clinic at the Juvenile Court of the Second District of Connecticut over a two-year period were adopted (the incidence of adopted children in the general population is less than 1 percent [1]). The parents of these 7 adopted children were extraordinarily rejecting toward them by the time they reached the juvenile court.

During the same period of time, we saw 26 allegedly neglected children who were referred to the clinic. Contrary to our expectations, their parents seemed to be extremely attached to and protective of them. These neglected children seemed to be especially prone to multiple and serious delinquent acts, but they received what appeared to be particularly gentle treatment from the juvenile justice system. We felt that the adopted children, who had less serious histories of delinquency, received far harsher treatment. This paper represents a systematic investigation of these clinical impressions.

Drs. Dorothy and Melvin Lewis and Dr. Balla are with the Child Study Center, Yale University, 333 Cedar St., New Haven, Conn. 06510, where Dr. Dorothy Lewis is Assistant Clinical Professor of Psychiatry, Dr. Balla is Research Associate, and Dr. Melvin Lewis is Professor of Clinical Pediatrics and Psychiatry. Mr. Gore was an undergraduate at Yale University at the time this work was done.

This work was supported by grant A70-9001-108 from the Connecticut Planning Committee on Criminal Administration and the Law Enforcement Assistance Administration.

METHOD

Our subjects were the 7 adopted and 26 neglected children referred to the juvenile court clinic during a two-year period. We gathered the following data for each group: type of disposition made by the court, number and severity of delinquency offenses, court clinic diagnosis, delinquency history of siblings, criminal and psychiatric treatment history of parents, family intactness, and age at adoption (where applicable). Severity of offenses was coded on a 3-point scale (1 = acts not criminal by adult standards, 2 = offenses against property, and 3 = offenses against person). In all comparisons of the two groups on these variables using chi-square analysis, Yates's correction for discontinuity was applied. Our clinical observation of the children and their families augmented these statistical data.

RESULTS

Our impression that the adopted children received harsher treatment in the court than the neglected children was confirmed. Only 1 of the 26 children in the neglected group (3 percent) was placed in a correctional institution (the most severe disposition available to the juvenile court), while 3 of the 7 adopted children (41 percent) received this disposition. The difference between these proportions is significant ($\chi^2 = 4.64$, $p < .05$). In addition, 3 of the 4 remaining adopted children received dispositions that removed them from their homes, and application was made for the 7th child to move into a residential placement. Few of the neglected children were ultimately removed from their homes.

This difference in dispositions may have been due to a variety of factors unrelated to adoptive status per se. For example, children in the adopted group might actually have committed more delinquent acts or more serious ones than children in the neglected group. We therefore compared the number and seriousness of offenses for the two groups, and found no differences between them in either variable. The adopted children committed an average of 8.71 delinquent acts, compared with an average of 9.27 for the neglected group ($t = .74$).

It was also important to determine whether the two groups of children displayed different degrees of

delinquent behavior, which could account for the differing dispositions they received. In the case of both type 1 (childhood offenses) and type 2 (property offenses), no significant differences were found. However, while there were no acts of violence (type 3 offenses) committed by adopted delinquents, 4 of the 26 neglected children committed such offenses. Although these numbers are not amenable to ordinary statistical treatment, the fact that 15 percent of the neglected children committed violent acts is noteworthy for two reasons. First, the adopted group received harsher treatment, despite the fact that they committed no violent acts. Second, neglected delinquent children would seem to be an especially important target population for efforts directed toward the prevention of violent and aggressive behavior.

The adopted children may have been given harsher dispositions in response to particularly disruptive behavior arising from their more disturbed psychological state. We found the severity of psychiatric impairment in the two groups to be similar, based on criteria reported in an earlier article (2): 2 of the 7 adopted children and 5 of the 26 neglected children demonstrated psychotic symptoms, proportions that are not significantly different ($\chi^2=0$).

Another possible explanation for the court's discrepant treatment of the two groups would be that adopted children's siblings were also delinquent, which would make removal from the home to an institution appear to be in the child's best interest. However, this was not the case. Not one of the 9 siblings of adopted children was known to the juvenile court, but 38 of the 82 siblings of neglected children had delinquency records, a significant difference ($\chi^2=5.38$, $p<.05$). (The biological relationship of the siblings in both groups was unknown in many cases.)

The decision to remove children from their homes could have been related to parental criminality or parental psychiatric disorders. This was not the case, as no adopted child had a parent with a criminal history, while 13 of the 26 neglected children came from families in which there were criminal records, a statistically significant difference ($\chi^2=3.87$, $p<.05$). Thus, having a criminal parent did not predispose the neglected child to placement in a correctional facility. We also found that 2 of 12 adoptive parents and 12 of 46 neglecting parents whose names and birthdates were known had been treated at state psychiatric facilities. The difference between these proportions was not statistically significant.

We wondered if children from nonintact families would be more likely to be sent to correctional institutions because of their parents' inability to act cohesively on their behalf. We found, however, that a significantly greater proportion of neglecting familes (18 of 26) than of adoptive families (1 in 7) were not intact ($\chi^2=4.75$, $p<.05$).

The difference in dispositions could not be explained in terms of conventional factors related to race or social class. All of the adoptive parents were white, whereas approximately one-third of the parents of the neglected children were black. The majority of adoptive parents were middle-class, while most of the neglected children came from lower-class backgrounds.

It would seem that the differences in dispositions were not accounted for by differences in delinquent behavior or by criminal, psychiatric, or socioeconomic factors in either the children or their parents.

The final factor we investigated was age at adoption. At least 5 of the 7 adoptions took place after infancy: 3 children were adopted at approximately two years of age (1 of the 3 was then given up and adopted again later), 1 child was adopted at age three, and 1 child was five years old at the time of adoption.

DISCUSSION

Our findings led us to conclude that some factor that was not amenable to quantitative analysis was operating in this situation. We felt that this factor was probably peculiar to adoption. It seemed that reciprocal attachment between parent and child, which is considered crucial to normal adaptation, was not strong enough under certain circumstances of adoption to resist the stresses of a particularly difficult adolescence.

It would be inaccurate to assume that the adoptive parents of delinquents had always rejected their children, since 5 of the 7 sets of parents had sought psychological assistance for their children prior to court referral. Two families had gone to child guidance clinics, two to private therapists, and one couple had obtained private psychiatric hospitalization and special schooling for their child. Many of these families had participated in lengthy therapeutic endeavors. In spite of this, by the time the adoptive family reached the juvenile court, the parents were blatantly rejecting toward their children. Two families had even hired lawyers in attempts to nullify long-standing adoptions. This contrasts with the behavior of most parents involved with the court (including neglecting parents), who ordinarily use lawyers to defend their parental rights. Two other adoptive parents refused to come to the court clinic to assist in therapeutic dispositions, despite the fact that their children were seriously disturbed and required psychiatric intervention. A few adoptive parents requested placement for their children in correctional institutions.

The adopted delinquent indeed did not have a friend in court. One basic function of a parent in the juvenile court is to defend and protect his child's interests. The so-called neglecting parents, by and large, mustered their forces to perform this crucial function. Although these children were often physically and psychologically neglected because of home lives that were generally chaotic, the conscious attitude of their parents was not neglectful or hostile.

Exploration of causality in the ultimate disintegration of the bond between parents and adopted delinquents leads to consideration of some very difficult issues in parent-child relationships. These issues involve the relative contributions of intrinsic vulnerabilities, experiential factors, and unconscious fantasies. It is too simplistic to conclude that either the parents' malignant attitudes or a child's particular problems alone determined the unfortu-

nate outcome of these cases. Rather, it seems that a combination of factors, including age at adoption, contributed to the ultimate fracture of family bonds.

Intrinsic Vulnerabilities

There is ample evidence from retrospective studies that adopted children are more prone to psychiatric problems than the general population. Mikawa and Boston (3) reported that although less than 1 percent of all live births result in adoption, the percentage of adoptees known to three California psychiatric institutions over a five-year period ranged from 4 percent up to 9.6 percent. Toussieng (4) noted that 10.9 percent of all children seen at the Menninger Clinic over a five-year period were adopted, and Schecter (5) reported that 13 percent of his patients in private practice were adopted. The incidence of adopted children referred to the court clinic (2.5 percent) also exceeds the incidence in the general population. The reasons for this overrepresentation are complex.

The question of whether intrinsic vulnerabilities of adopted children account for subsequent emotional disturbances remains controversial. Rosenthal and associates (6) examined the genetic and environmental factors contributing to the development of schizophrenia in groups of adopted children. They documented the greater likelihood of schizophrenia developing both in the biological children of schizophrenics adopted into nonschizophrenic families and in children of nonschizophrenic parents who were adopted into schizophrenic homes. Scott (7) reported Mednick's finding that there was a greater association between the criminality of biological fathers and their adopted-away sons than between adoptees and their adoptive fathers.

These findings, although accepted by some, have been questioned. Bohman's findings in a follow-up study of adoptees (8) suggested that "psychological or social insufficiency in the biological mothers was not reflected at all in maladjustment among the children" (p. 218). In addition, he found no relationship between criminality in biological fathers of adoptees and the subsequent adjustment of a child in an adoptive home.

Parental Attitudes and Characteristics

There is some evidence that parental attitudes and characteristics are crucial factors in the adjustment of adopted children. Lawder and associates (9) noted that when parents are critical of their adopted children for any reason during the supervisory adoption period, later parent-child adjustment tends to be less successful than it is when parents are pleased during the first months. Bohman (8) has also cited the personal characteristics of adoptive parents as very significant factors in the child's future adjustment. Mikawa and Boston (3) found that although there was a greater incidence of emotional disturbance in adopted children than in biological offspring, this more often resulted from parent-child interactional difficulties than from problems specifically related to adoption.

Pemberton and Benady (10) described 12 cases in which pathological interaction between children and parents eventually led to removal of the child. In these families, the rejected child was particularly aggressive and negativistic toward his parents, and the parents had unstable marriages. These children (only one of whom was adopted) also manifested more lying, stealing, enuresis, and encopresis than a comparison group. It is not clear from Pemberton and Benady's study, however, whether the child was rejected because he was intrinsically more difficult to control than other children in the home or whether the child's negativistic behavior was a response to early parental rejection.

Since there were similar antisocial behaviors and degrees of pathology in the neglected and adopted children in our study, one must ask what other factors might have contributed to the formation of tenuous parent-child attachments in the adopted children. There is evidence that parents tend to form less than optimal attachments to children they perceive to be less than perfect in several areas. The infant is normally a determinant of some of the mother's behavior (11). For example, eye contact seems to foster positive maternal feelings (12), and certain types of early behavior (e.g., crying, following, clinging, and sucking) appear to act as "releasers," stimulating instinctual responses in the mother (13). However, when the child has a defect (blindness, for example), the parents may experience unconscious revulsion toward the child that is manifested as severe avoidance (14). Kanner (15) attributed the autistic behavior of infants to cold, unresponsive mothers; since his work was done, the child's contribution to the mother's unresponsiveness has been increasingly emphasized (16).

Because all of the studies we have described in this section highlight interactional factors leading to parent-child difficulties, they encouraged us to search for possible analogous, if not identical, factors operating in the parent-child relationships of adopted delinquents. Several of the adopted delinquents had arrived at their new homes with a variety of physical and emotional problems. Two were covered with unsightly sores and one, adopted at eight days of age, was recovering from head surgery of an undetermined nature when he arrived at his adoptive home. One child had been sexually assaulted several times prior to adoption. However, parents of neglected children with comparable physical and emotional problems were possessive of them.

Age at Adoption

Another factor that was probably significant was the lateness of adoption: 5 of the 7 children were adopted after their second year. According to Yarrow (17), children placed in adoptive homes when they are younger than six months demonstrate fewer atypical behaviors than those adopted after that age. Casler (18) noted the extremely deleterious emotional effects of placement between six months and one year of age. Bowlby (13) and Spitz and Wolff (19) found emotional difficulties subsequent to the disruption of an ongoing relationship during critical periods of infant development. Lawder and associates (9), however, did not find an association between later placement and poor outcome of adoption. Furthermore,

Kadushin (20) cited numerous studies documenting the resiliency of children and the possibility of reversing the effects of early emotional deprivation.

CONCLUSIONS

We believe that neither acquired nor intrinsic defects alone caused the extreme rejection of the adopted children by their parents; nor was the factor of late adoption alone sufficient to fracture the parent-child bond. Rather, it is likely that late adoption coupled with perceived (and often real) defects in the children prevented parental attachment from becoming strong enough to weather the stresses of disruptive adolescent behavior. These older and often perceptibly damaged youngsters could not evoke the intense parental response necessary to forge an indissoluble bond between parent and child. Paradoxically, most of the adopted children were intensely attached to their parents and were therefore significantly affected by the rejection.

Our findings have practical implications for dealing with adopted delinquents in court. The evidence that adopted delinquents lack a friend in court makes it incumbent on probation and judicial personnel to be alert to their special problems and to ensure that they are provided with an understanding advocate to defend their interests. The question remains whether any court-appointed individual can approximate or substitute for the intense advocacy of a parent.

Prevention in Mental Health: A Controlled Study

BY PAUL R. POLAK, M.D., DONALD EGAN, M.D., RICHARD VANDENBERGH, M.D., AND W. VAIL WILLIAMS, PH.D.

The authors conducted a controlled study in which families who had experienced the sudden death of a family member were given crisis intervention services and compared at follow-up with two untreated control groups. Results did not support the hypothesis that such services decrease the risk of psychiatric illness, disturbed family functioning, or increased social cost to the families. The authors suggest that environmental and social systems factors and individual variables are powerful predictors of outcome in bereavement.

CRISIS STATES have often been pinpointed as opportune points of focus for preventive mental health programs (1). Rees and Lutkins (2) and others (3) have found a significant increase in the risk of morbidity and mortality within the first year after the death of a family member. To test the hypothesis that preventive crisis intervention would decrease the risk of incidence of psychiatric illness, physical illness, and social disturbance, such services were provided to 39 families after a sudden death.

METHOD

Crisis Intervention

Treatment began when intervention team members accompanied the medical examiner of the Denver County coroner's office to the homes of the surviving members, usually within 1 to 2 hours after the death. The first meeting with the family lasted from 1 to 6 hours; intervention techniques varied from arranging supervision for children to assisting in notifying relatives and helping families to work through their grief.

Families were seen for 2 to 6 sessions over a period of 1 to 10 weeks, and crisis intervention techniques were used within a social systems framework (4). Treatment focused on increasing the effectiveness of the family in coping with feelings, decisions, and problems of adjustment related to death (5). Intervention took place within the boundaries and values of the social system in its natural setting rather than following a formal psychotherapeutic format. Therapeutic telephone interactions were employed regularly and frequently.

Experimental Design

The research design involved three subject groups: an experimental group of 39 families who received crisis intervention following a recent sudden death, a control group of 66 families who received no crisis intervention following a recent sudden death, and another control group of 56 families who had experienced no death within 2 years prior to contact and who received no crisis intervention.[1]

Families who experienced a recent sudden death were randomly assigned to the experimental (treated) group or to the control (untreated) group. All groups (including the nonbereaved control group) were matched for age, socioeconomic status, education, and residential location.

Outcome Measures

Outcome measures were collected at 6 and 18 months after the death by an independent research team that used three data collection techniques. Self-report questionnaires were related to: 1) physical illness, measured by the Cornell Medical Index (6); 2) psychiatric illness, measured by the Minnesota Multiphasic Personality Inventory, the Stirling County questionnaire (7), Beck's depression scale (8), and questions adapted from the Boston bereavement project (3); 3) family functioning, measured by the Ferriera and Winter unrevealed differences technique (9) and the Bodin free-drawing technique (10); 4) crisis coping, measured by a questionnaire developed by project staff to obtain stress levels specific to bereavement adjustment problems; and 5) intellectual functioning, measured by Harvey's Conceptual Systems Test (11). Evaluation ratings involved interviews with family members on such matters as overall family functioning, depression, physical and mental health (based on direct interviews with family members conducted by a psychiatrist), and socioeconomic and social well-being. Social cost questionnaires examined pre/post income, expenses, indirect costs, and/or losses. All the raw data

Egan and VandenBergh are with the University of Colorado Medical Center, where Dr. Egan is Assistant Clinical Professor of Psychiatry and Director of the Drug Rehabilitation Program and Dr. VandenBergh is Clinical Associate Professor of Psychiatry. Dr. Williams is Research Psychologist, Fort Logan Mental Health Center, Denver, Colo.

[1]Both control groups were free to make use of psychiatric help outside the project, and, in fact, a very small proportion of families in both control groups sought psychiatric help.

collected soon after the death and at the 6-month interval were subjected to a principal components factor analysis; the 13 stable outcome factors that were identified are listed in appendix 1.

RESULTS

The results of the 18-month data collection will not be reported in this paper. Our discussion of the 6-month data analysis involves three areas: 1) 6-month outcome data evaluating the efficacy of crisis intervention as a preventive technique for families experiencing acute bereavement; 2) the effects of the crisis of sudden death on subsequent physical, mental, and social functioning by comparing the outcome of families who experienced a sudden death with those who did not; and 3) our clinical observations on the interaction among environmental, social systems, and individual variables.

Efficacy of Crisis Intervention

Data analysis of the sampling characteristics of the treated and untreated bereaved groups revealed more suicidal deaths ($F=5.1$, $p<.025$) and a higher degree of suddenness of death ($F=9.8$, $p<.002$) in the treated group. It appears that the deputy coroner unwittingly selected a greater proportion of families in which the death was suicidal or accidental (and therefore more sudden) for clinical intervention by the project staff. Initial analysis of the data suggests that the treated group had poorer outcomes than the untreated group. However, when the proportion of accidental and suicidal deaths was held constant in an analysis of covariance, the differences between these two groups disappeared; i.e., 6 months after the death there were no major statistically significant differences between the bereaved families who received treatment and those who did not. The untreated bereaved group did, however, exhibit significantly less concern than the treated group over their socioeconomic and social well-being 6 months after the death ($p<.004$).

In summary, the 6-month outcome data analysis suggests that the crisis prevention program did not improve coping behavior or lower the incidence of medical and psychiatric illness or of disturbed social functioning in bereaved families.

Comparison of Bereaved and Nonbereaved Families

Preliminary data analysis on the sampling characteristics of the bereaved and nonbereaved groups revealed that the nonbereaved group had a better social and personal adjustment prior to participation in this project ($F=60.2$, $p<.001$) than the death-related groups. We therefore utilized an analysis of covariance on the 6-month outcome data for the factors listed in appendix 1 in order to make the bereaved and nonbereaved groups more comparable. Our results indicated that 6 months after a death family members in both bereaved groups showed poorer functioning in several areas than nonbereaved families—both groups of bereaved families had significantly greater acting out (pathological emotional expression)[2] ($p<.05$), greater depression ($p<.001$), and greater problems in family, intrapersonal, interpersonal, and social functioning (crisis coping) ($p<.05$).

Clinical Observations

The sudden death of a family member appeared to have a far-reaching impact on the survivors; however, short-term crisis intervention aimed at strengthening interpersonal and intrapsychic adaptation to the death apparently did not. Some of our observations on the interaction among environmental, social systems, and individual variables may lay the groundwork for an initial interpretation of this challenging finding.

Death as an environmental stimulus. There seemed to be a high correlation between poor outcome (measured by the development of physical or mental illness or serious social disruption in the family) and the following tragic circumstances: 1) degree of suddenness, 2) degree of violence, 3) direct observation of the death and the occurrence of the death in the home, 4) suicidal death, 5) death of a child under 12, and 6) family members directly or indirectly contributing to the death. On the other hand, when there had been heavy burdens on the family resulting from a family member's chronic debilitating illness or chronic economic and social burdens (such as those imposed on a family by a socially disruptive, chronically ill alcoholic), death seemed to alleviate stress, and the adjustment of family members to the death was less difficult.

Social systems factors. It is our impression that in cases of sudden death a family must be able to carry out a number of organizational tasks in order to adjust to the death. One of the most important of these tasks is role reallocation. To accomplish this, family members must first be able to realistically appraise the roles the decedent had played in family life and to define which of these roles could be assumed by surviving family members; then, the roles must be reallocated within the reconstituted family group at an appropriate time. These roles include not only instrumental roles such as breadwinner and disciplinarian but also expressive roles such as communications facilitator and mediator.

In view of the complexity of role reallocation and other organizational tasks after the death, the familial characteristics that were associated with good outcome are not surprising. For example, families with a high degree of effective communication and flexibility or those who had previously exhibited a high degree of problem-solving capacity tended not to develop physical or mental illness or disturbed social functioning. Outcome was also favorable in families who could call on an effective network of formal and informal social resources outside the family.

[2]There was a significant family main effect ($F=11.9$, $p<.001$)—the younger the individual, the more acting out. There was no significant family × death interaction.

The families who lacked these positive characteristics tended to experience poor outcome.

Special roles played by the decedent prior to his death also tended to be predictive of outcome. For instance, when the decedent had played an expressive role (such as scapegoat, delinquent, or mental patient) that communicated about an ongoing family conflict and at the same time served to keep the conflict in balance, his death often resulted in mental and physical illness and social disruption for family members. The negative effects were magnified when the circumstances of the death itself served to intensify and potentiate the unresolved family conflict.

Certain religious convictions tended to promote externalization. Family members who belonged to fundamentalist religious groups had incorporated highly structured explanations of the causes of death and of man's fate after death. Family members attributed the death to God's will and refused to discuss any facet of their realistic involvement in the death or to elaborate on specific grief reactions. These families would be considered in psychiatric terms to be using denial quite extensively and, at times, pathologically. Yet up to two years after the death they appeared to maintain good physical and mental health ratings and appeared to be benefiting from this defense.

Individual factors. Preliminary data suggest that the individual's degree of unexpressed feelings of hopelessness and despair, combined with his crisis-coping ability and tendency to discharge emotional conflicts through somatic dysfunction rather than behavioral dysfunction, were predictive of the development of serious physical and emotional illnesses. These results support the findings of previous retrospective studies (12–14).

From the interview data, it is our impression that other variables are also predictive of subsequent serious illness. Individuals who are able to maintain a healthy level of denial have a better outcome, and the predictive value of individual variables is enhanced when they are considered in combination with environmental, family, and social systems variables.

Interaction of environmental, social systems, and individual factors. Perhaps our most important observation was the crucial interaction among environmental, social systems, and individual variables in determining outcome. A review of our case notes indicated that among families rated comparable on social systems variables, those who experienced deaths under conditions of greater environmental stress showed a poorer bereavement outcome. Similarly, when environmental factors seemed comparable, the family with negative social systems patterns tended to experience poorer outcome. Finally, in those instances when the environmental factors, social systems factors, and individual characteristics were all predisposed toward poor outcome, the risk of illness and social disturbance was very high.

Conversely, it often seemed that the effects of particularly negative environmental variables around a death could be counteracted by a flexible family system with impressive communication and problem-solving skills; the same tragic circumstances occurring in a fragmented, uncommunicative family would lead to poor physical and mental health after the death.

CONCLUSIONS

Our results did not support the hypothesis that a preventive crisis intervention service would decrease the risk of psychiatric illness, disturbed family functioning, and increased social cost for families experiencing acute bereavement. (This finding does not imply that crisis intervention is ineffective as a preventive technique in other crisis situations.) At the same time, families in which there had been a more sudden death showed much greater evidence of mental illness and other negative outcome factors six months after the death.

These data and our clinical observations suggest that environmental forces play a much greater role in determining outcome than is often believed. Social systems factors also seem to be important intervening variables in influencing outcome, but existing techniques of crisis intervention are not effective in producing significant constructive social systems changes in situations such as sudden death. It is hoped that continued study will clarify the interaction among environmental, individual, and social variables and lead to more effective techniques of preventive intervention.

Prompt Publication Policy

The *Journal* would like to remind those authors who are particularly interested in early publication (whether to establish priority of an idea, reveal innovative results of new research, or for other pressing reasons) of its prompt publication policy, first announced in the April 1971 issue (p. 1399) as follows:

"The *Journal* would consider publishing very short (two- to four-page) manuscripts in the first available issue. Of course, these manuscripts will still have to undergo expert scrutiny before being accepted, and two months must be allowed for the printing process, but we think we can considerably shorten the time required for the publication of these very short articles, which will be included in the Brief Communications section."

Authors who would like to have their manuscripts considered under this policy should indicate this desire, as well as the reasons for it, when they submit their manuscripts.

Suicide in the Psychiatric Hospital

BY DONALD A. SCHWARTZ, M.D., DON E. FLINN, M.D., AND PAUL F. SLAWSON, M.D.

The authors note that although the psychiatric hospital is often used as a means of preventing the suicide of disturbed patients, some hospitalized patients succeed in committing suicide; such an event is distressing for hospital staffs as well as for patients and families. However, the authors believe that the occasional occurrence of in-hospital suicide is inevitable. They present data on the frequency and characteristics of suicides among hospitalized psychiatric patients in Los Angeles County during the period from 1967 to 1972.

IT MAY SEEM difficult to understand how a patient could commit suicide in a psychiatric hospital. As the wife of one patient said when she was told he had done so, "But that was why we sent him there." Nevertheless, in our view there is no way that one can prevent a person intent on suicide from completion of the act. That so many "suicidal" persons are deterred testifies more to their ambivalence than to the capacity of others to prevent suicide. Not hospitalization, one-to-one surveillance, seclusion, or physical restraints will prevent suicide if the patient is determined to commit it.

The frequency of suicides in psychiatric hospitals is not well known. Most articles on the subject are based on data from a particular hospital or hospital system. Farberow and associates (1, 2) derived a great deal of data from Veterans Administration hospitals. (Their work dealt with suicides in general medical and surgical hospitals as well as in neuropsychiatric hospitals.) Sletten and coworkers (3) reported on suicides in the Missouri state mental hospital system, and Kirven (4) presented data on suicides in the Virginia state mental hospital system. Several other reports (5–8) dealt with the experience at individual hospitals. Temoche and associates (9) reviewed all suicides in Massachusetts for a three-year period (1949 to 1951). They wished to compare the suicide sample with the general population, but because the data on the general population available to them covered only the white population, they excluded data on nonwhite suicides from their report. None of these studies reported on the total hospital population of a geographic area in the United States.

Two Scandinavian authors provided data on mental hospital suicide incidence in total populations. Ødegård (10) reported on mortality in general in Norwegian mental hospitals during the years 1926 to 1941. Among the causes of death, he separated out a group of "unnatural deaths," the majority of which were suicides. Definite suicides were reported as one subgroup and other unnatural deaths as another; some of the latter group were probably unproved suicides. Achté and coworkers (11) reported on suicides committed in psychiatric hospitals in the mental health district of Helsinki, Finland. Their study, covering the years 1952 to 1963, is the most recent total area study of suicide in mental hospitals.

SCOPE OF PRESENT STUDY

We were curious to know how often patients completed suicide in hospitals in our own area and what the characteristics of such patients were. Since suicide is a sensitive topic, we anticipated a reluctance of hospital staff to reveal pertinent data; therefore, we decided to use an anonymous questionnaire rather than an identified inquiry. But that raised the question of failures to respond. Confidence in the data would depend on securing the largest possible percentage response. For this reason, we began our study by telephoning the chiefs of staff, administrators, or medical directors of all hospitals with psychiatric beds in Los Angeles County to tell them about the study and to solicit their cooperation. The contacts were made, whenever possible, by one of us who knew the person being approached. The questionnaire was mailed to the hospital only after we had secured the cooperation of the potential respondent and answered any questions. In all cases the questionnaire was addressed to the person who had agreed to be responsible for its completion.

No one refused to participate or showed overt reluctance. However, in spite of this apparent cooperative spirit, 6 of the 33 hospitals to which questionnaires were sent did not return them, even after a follow-up letter. Some hospitals returned the questionnaire only after personal follow-up contacts. (This was possible in spite of the anonymity of response because some of the hospitals

Computing assistance was obtained from the Health Sciences Computing Facility, UCLA, sponsored by Special Research Resources grant RR-3 from the National Institutes of Health. Programming assistance was provided by the Mental Retardation Program Computing Resources Group.

The authors wish to extend special thanks to Judy Klusza.

were unique in size and type of sponsorship and thus were inevitably identifiable.) Although we had originally wanted to survey a larger area than Los Angeles County, we limited the study to that region in order to increase the probability that one of us would have sufficient personal relationships with the staff of each hospital, thus increasing the likelihood of a response. Because our return rate was only 80 percent in spite of all these efforts, we concluded that our limitation of the geographic scope of the study was wise.

METHOD

Each psychiatric hospital and each general hospital in Los Angeles County with a psychiatric inpatient unit was included if the facility had been in operation for at least one year. Each was asked to fill out a sheet indicating whether any patients had committed suicide while they were carried on the hospital books during the period of January 1, 1967, to May 1, 1972. If so, we asked how many such suicides had occurred in the hospital, how many on authorized leave, and how many on unauthorized leave. Certain basic information concerning the facility was asked for, particularly its sponsorship and general size. Further details were not requested because we wished to ensure the anonymity of the data and thereby increase the percentage of response.

In addition to this information we requested that a case report be filled out on each case of suicide (up to five cases), giving a variety of information about the person and the circumstances of his or her illness and suicide. We asked for age, sex, marital status, occupation, diagnosis, and acuteness or chronicity of the illness for which he or she had been hospitalized. We asked where the suicide occurred, by what method, how well it was investigated, whether it might have been prevented, whether any changes in policy were made afterward, and whether litigation over the suicide had occurred.

RESULTS

Los Angeles County had 33 hospitals that met all of our criteria. Of these, 2 were state hospitals, 3 were VA hospitals, 3 were county hospitals, 14 were nonprofit private hospitals (some of them forming parts of community mental health centers), and 11 were proprietary hospitals. Of the 33 hospitals, 27 returned the questionnaires; these 27 included all of the public facilities. Four of the 14 private nonprofit hospitals and 2 of the 11 proprietary hospitals failed to return their questionnaires. Based on the hospitals returning questionnaires, the bulk of the suicides occurred in public hospitals. If the 6 nonresponding private hospitals were typical of the entire private sector, their failures to respond would not greatly affect the conclusions of the study. However, it is possible that these 6 hospitals failed to respond precisely because they did not want to reveal high rates of completed suicide and did not trust the anonymity of the study.

Of the responding hospitals, 3 had censuses over 200, 9 had censuses between 50 and 200, and 15 had censuses below 50. The hospital census data obtained from the Mental Health Division of the Los Angeles County Department of Health Services indicated that 4 of the nonresponding hospitals would have had censuses between 50 and 200 beds and that 2 would have had censuses below 50 beds.

Of the 27 hospitals responding, 14 had had at least one suicide during the study period and 13 had had none. The 13 hospitals with no suicides were 1 county, 6 private nonprofit, and 6 proprietary facilities. There had been a total of 49 suicides in all responding facilities, 26 of which had been committed in the hospital, 14 while the patient was on authorized leave, and 9 during unauthorized absences.

When we planned the study, we had no idea how many patients might have committed suicide in any one hospital. We were concerned that a hospital which had many suicides might fail to respond if asked to fill out a two-page report on each case—simply because of the work involved. To avoid such a possibility, we asked for case reports on only the last 5 cases. As it turned out, the largest number of cases in any one hospital was 8; two hospitals reported more than 5 cases—one VA hospital reported 6 and one state hospital reported 7. Of the total of 49 cases, we received individual case reports on 45. The balance of the data to be reported in this paper relates to those 45 cases.

Of the 45 cases, 31 were men and 14 were women. The median age was 37 years, with a range from 19 to 88 years; 28 (62 percent) were between 25 and 49 years old. We obtained marital status information on 44 cases—12 were single, 25 were married, 6 were divorced, and 1 was separated. According to our occupational data, 5 patients were in artistic or professional occupations, 1 in a technical field, 4 in managerial positions, 6 in sales or clerical work, 3 were craftsmen, 2 were service workers, 2 were laborers, 9 were housewives, 6 were students, and 7 were in unknown occupations or unemployed (including a few veteran patients whose only known occupation had been their military service).

Diagnostic data revealed a variety of diagnoses, with the majority falling into the schizophrenias and the affective disorders. The precise breakdown is shown in table 1. Thirteen of the patients were judged to be acutely ill, 27 chronically ill, and 5 were reported to be both acutely and chronically ill.

Of the 45 patients on whom individual reports were obtained, 23 had committed suicide in the hospital, 13 on authorized leave, and 9 on unauthorized leave. Of those who suicided in the hospital, 15 had been on a locked ward, 7 on an unlocked ward, and 1 in a private room. Of the in-hospital suicides, 6 had been on suicidal or special observation and 14 had not; in 3 cases, there was no response to this question.

Reports of method of suicide showed the usual preponderance of hanging that has been reported in every hospital suicide study we have seen in the literature. Hanging was the mode of suicide in 17 of the 45 cases,

TABLE 1
Type and Frequency of Diagnosis

Diagnosis	Number (N=45)
Schizophrenia	17
Paranoid	7
Schizo-affective	5
Acute	2
Chronic	3
Depression	20
Manic-depressive	2
Involutional melancholia	3

Depressions	1	15	4	20
Other diagnoses	4	3	1	8

*Significantly different among the three diagnostic groups (p=.02, chi-square analysis).

with a wide dispersion of other modes (see table 2).

Thorough or exhaustive investigations of the suicide were made in 30 of the 45 cases, and cursory or no investigations were made in the other 15. It might be assumed at first that the thoroughness of investigation would be largely correlated with location of the suicide (i.e., exhaustive for in-hospital suicides and cursory for those away from the hospital). In fact, however, the degree of investigation appeared to be hospital-related. The 15 cases with no investigation or a cursory one consisted of 8 of the 13 VA cases, 5 of the 8 private nonprofit cases, only 2 of the 12 state hospital cases, and none of the cases from county or proprietary hospitals. In contrast, the 30 thorough or exhaustive investigations consisted of 10 of the 12 state hospital cases, all of the 8 county hospital cases, all of the 4 proprietary hospital cases, only 5 of the 13 VA cases, and 3 of the 8 private nonprofit cases.

In 40 of the 45 cases, respondents made a judgment as to whether the suicide could have been prevented. In 9 of those 40 cases there was definite or strongly suggestive evidence for preventability, and in 31 cases there was either equivocal or no evidence. Interestingly, 8 of the 9 cases judged to have been potentially preventable were from state, county, or proprietary hospitals, i.e., those which had made more thorough investigations of the circumstances of suicide. Perhaps expectably, 8 of the 9 were in-hospital suicides.

The suicide resulted in litigation in 10 cases; 9 of the 10 entailed the filing of a lawsuit. Of the 10 cases, 6 had been settled for less than $100,000 each (without any of them going to trial) and 4 cases remained unsettled at the time of this study. We will be reporting the data on litigation in more detail in another paper.

When variables were cross-tabulated against each other, no significant correlations were found. Interestingly, choice of method did not correlate significantly with sex. VA patients suiciding outside the hospital often used firearms (as has been reported previously); 5 of the 7 gunshot cases were VA patients, 1 of whom was a woman. The 3 drug overdose cases involved men.

Diagnostic categories were then collapsed and a cross-tabulation was made of the broad categories against other variables. Diagnoses were classified as schizophrenias, affective disorders (psychotic and neurotic), and all others. This set of cross-tabulations showed one statistically significant finding—the relationship of acuteness or chronicity to collapsed diagnostic categories (see table 3). Only 1 case of affective disorder was classified as acute only, while almost half of the schizophrenic cases and half of the "other" cases were judged to be acute only. This difference was statistically significant (p=.02, chi-square analysis).

The median age was 29 in the schizophrenic group and 42 in the depressive group, with the other group intermediate, but the distributions were not significantly different.

DISCUSSION

Since our data are derived from questionnaire responses with only 80 percent return, we cannot draw any firm conclusions about rates of hospital suicide. Moreover, some cases may not have been reported because of simple forgetfulness since most hospitals did not have a

formal system for storing data on hospital suicides as a class. However, the fact that we have responses from 80 percent of the hospitals in a total county area covering hospital suicides for a period of five years and four months permits us to draw some tentative conclusions.

As a generalization, we can say that the frequency of hospital suicides is not very great. An 80 percent sample of all psychiatric facilities in Los Angeles County, with a total county population of 7.5 million, yielded fewer than 9 suicides a year. Almost half of these were patients on leave or unauthorized absence from the hospital. Suicides in psychiatric hospitals are generally reported to be most frequent in patients diagnosed as schizophrenic. However, most of the reports in the literature have been from large public hospitals, where schizophrenia is the most common diagnosis in the hospital population in general.

Our own study revealed only one-third of the cases with a schizophrenic diagnosis, but our data are derived from a wider range of inpatient facilities than is true of most studies. In the community in general, the preponderance of diagnosis is not as heavily schizophrenic as in the large public facilities. Our data show the usual preponderance of men over women that is reported in hospital and other suicide samples. We found much the usual distribution of methods for hospital suicides.

We wonder whether the relationship of chronicity to depressive suicides as contrasted with suicides of patients in schizophrenic and other diagnostic categories reflects something we have mentioned before (12), namely, that hospital staffs and patients alike tolerate intensive observation of the acutely suicidal patient for brief periods but that long continued close observation produces stress and evokes resentment. Suicides by schizophrenics are generally less predictable and preventable than those associated with depressive disorders for a variety of reasons. The acutely depressed patient generally gives warning of his suicidal preoccupation and may be deterred from the impulse by the protective responses of hospital staff members. However, the chronically depressed and suicidal patient may be reacted to as the "boy who cried wolf" and assumed to be a lesser risk than he really is. This is especially likely after long periods of suicidal preoccupation or threat, or after numbers of previous attempts.

We were struck by the unpredictability of most of these suicides. Although some cases were judged on the basis of investigation to have been potentially preventable, most were not, even when examined retrospectively. Most of the patients were not on suicidal or special observation at the time of their suicides, although many had been under such observation in the past. Thus staff who were aware of past suicidality were not impressed with the current lethal intent of the patients.

The fact that only 49 completed suicides of patients carried on the current census of psychiatric inpatient facilities can be identified over a period of five years and four months is also noteworthy in regard to the problem of prediction. This is a small number of completed suicides out of a very large potentially suicidal population. There are no crucial characteristics that differentiate those who will suicide from those who might but will not. The small number of completed suicides makes identification of such differentiating variables difficult.

In evaluating the worth of suicide prevention measures, we need to weigh the desirability of preventing actual suicides against the deleterious effects of stringent suicidal observation on all the patients to whom it might be applied. As has been pointed out before by us (12) and others (13), there are disabilities, some potentially fatal, that may result from "overprevention," and these must be considered. Finally, we do not believe a person who is absolutely intent on suicide can be deterred from it. It is fortunate for the cause of suicide prevention that such unambivalent suicidality is the exception to the rule.

The Addict, Abstinence, and the Family

BY JOHN SCHWARTZMAN, PH.D.

The drug addict generally has an extremely difficult time terminating drug use and remaining abstinent. A partial explanation can be found in an investigation of the relative meaning of the drug for the addict within his social context rather than viewing the drug simply as a pharmacological agent. The idea that addiction is a social phenomenon within the addict's family suggests a relationship between the functioning of the families of addicts and their inability to tolerate abstinence. Because the abuse of heroin or barbiturates by one family member can result in "rewards" for all family members, the family, in behaving as if the addict cannot control his drug use, functions in such a way as to reinforce the addiction.

THERE IS GENERAL AGREEMENT in the literature on the structure of families of drug addicts and the effects of these families on the addiction of a family member (1). Most of the research on opiate addiction considers only the physiological effects of drugs and assumes that the structure of the family compounds the addict's physiological dependence because it reinforces his feeling of inadequacy and low self-esteem (2). However, if one assumes that the effects of any drug are modifiable by the context of drug use and by the characteristics of the user, a different explanation is suggested as to how the families of drug addicts function in relationship to the inability of addicts to tolerate abstinence.

This paper is based on an investigation of 21 predominantly white working-class families, each of which included at least one male heroin or barbiturate addict. These addicts were seen at an inpatient drug unit, an outpatient methadone clinic, and an outpatient mental health clinic. They ranged in age from 16 to 36, with an average age of about 23.

The familes were seen in from 1 to 22 one-hour psychotherapy sessions. Information was also collected in informal interviews with the addicts in these families and with other addicts.

My clinical impression was that there were no significant differences between the families of heroin addicts and the families of barbiturate addicts. Most of the heroin addicts used barbiturates occasionally, but very few of the barbiturate addicts ever used heroin. However, the barbiturate addicts were more likely to drink excessively.

Dr. Schwartzman is Research Associate, Family Institute of Chicago, 10 East Huron, Chicago, Ill. 60611.

The description of these families of addicts suggests that therapy should be reoriented toward seeing the locus of the problem as among family members or other significant others rather than in the addict. Therapeutic intervention in the addict's relationships with his addicted peers and with his family thus seems more promising than the more prevalent mode of group therapy among drug addicts.

LITERATURE ON FAMILIES OF ADDICTS

Almost all descriptions in the literature indicate that the addict's[1] relationship to his mother is the most important one for him within the family (3–5). The mothers were found to be overprotecting, controlling, and indulgent toward their sons (1, 3, 4). Most authors agree that the addict is more intimate with his mother than with his father and that the addict becomes used to gratifying the mother's emotional needs (1, 3–5). The mother then unconsciously strives to delay the maturation of the addict by infantilizing him (1, 3). There is also evidence (6–8) that other members of families of addicts have high rates of alcoholism and mental illness.

Although most of the literature on the families of addicts is consistent, the composite description does not seem to explain the dynamics of how families of addicts function or what this type of family has to do with drug addiction in particular. The composite description is similar to descriptions of families containing members with a wide variety of psychiatric symptoms (9–11).

THE PHARMACOLOGICAL FALLACY

The literature on the relationship between the addict's family and his addiction describes how a particular type of family produces an inadequate, immature individual who is unable to tolerate abstinence. There is also an assumption that the effects of heroin or barbiturates are so pleasurable and stopping is so unpleasant that addiction can be explained adequately in physiological terms. The addict's relationships with his family and peers are seen to be much less important than his physiological addiction in determining his ability or inability to tolerate abstinence.

Another implicit assumption seen in the literature is

[1]Unless otherwise stated, the addicts described in the literature were heroin addicts.

that drugs, which for the purposes of this paper I will define as any chemicals that affect the mind, have certain effects irrespective of the context of drug use or the characteristics of the user. This hypothesis is what Adler (12) termed the "pharmacological fallacy." There is evidence that it is indeed a fallacy.

Studies of the placebo effect contradict the pharmacological fallacy: they have shown that the context, including the state of the user, is an important determinant of the effects of placebo. Mechanic (13) stated that the two most important variables in placebo response are confidence in those who administer the placebo and a state of emotional arousal in those who receive it. It has been found (8, 14, 15) that a patient's expectation can greatly affect his physiological response, even to the point of reversing the pharmacological action of a drug.

Siegel (16) provided additional evidence against the pharmacological fallacy in his research on heroin use among American soldiers in Viet Nam. He found that withdrawal was universally benign and attentuated among the soldiers in spite of the fact that the heroin used in Viet Nam was often 25 times as potent as that sold on the street in the United States.

In another study (17) it was found that the attitude of the experimenter toward the subject strongly affects the analgesic effect of morphine. This study also found that the majority of normal individuals not experiencing pain find the effects of opiates unpleasant, that many who develop physical dependence in a medical situation tend not to resume taking the drug after withdrawal, and that a rapid development of dependence does not occur on short exposure to heroin.

Lindesmith (18, 19) argued that "addiction" is the result of the effects of withdrawal, but that the effects of the drug depend on a perception that has to be learned. If the individual does not realize that his condition is the result of withdrawal, he does not become addicted.

Addicts are willing to undergo privation and great expense and to enter into criminal careers to acquire their drug. They seem to be unable to tolerate abstinence. Heroin or barbiturates must have a very important function or meaning for addicts because they are willing to go through so much to acquire drugs that have variable context-dependent physiological effects. Since context influences the effects of drugs, it can be assumed that the social context of the addict is an important factor in the inability to stop using drugs. This becomes more obvious if one investigates the social effects of heroin or barbiturates within a most important social context, the addict's family.

THE FAMILY OF THE ADDICT RECONSIDERED

Most of the families of addicts in my sample had the same general characteristics as those described in the literature. However, if one views heroin or barbiturate abuse as a social phenomenon rather than merely the ingestion of chemicals, and if one considers the effects that the beliefs about drugs have on intrafamilial relationships, a different view of the addict's family emerges than the one described in the literature.

The beliefs about drugs that affect family relationships include the following: that it is difficult, painful, and dangerous to withdraw from drug use; that there is a euphoria or "high" gained by drug use; and, perhaps most important, that the addict's behavior is out of control. As a result of the last belief, it is assumed by both the addict and his family that he cannot stop using drugs and that he is not responsible for his behavior when he is under the influence of drugs.

The addict and his family also believe that he is unable to resist drugs if exposed to them. An example of the operation of this belief among addicts is the fact that almost all of the addicts I interviewed stated that they intended to develop friendships with "straight" people because they would not be able to remain abstinent if their friends used drugs.

An example of this belief occurred in a family with two barbiturate addicts. The drug problem was blamed on the neighborhood from which the family had moved because of the prevalence of drug use there. The assumption was that the fact that the boys had lived in that neighborhood inevitably led to their using drugs.

In all of the families in my sample, this feeling of powerlessness against drug use was reinforced by family members. If the addict was abstinent, other family members communicated in various ways the belief that this was a temporary condition.

As a result of the belief in the addict's powerlessness to refuse drugs, the mothers of these addicts felt that their alternatives were limited. They could refuse to let the addict remain at home and force him back to the street and into the company of other addicts, or they could allow him to stay at home and take care of him.

Parental Roles

The mother's role as the protector of the addict was reinforced by the father's demand that the addict stop using drugs and get a job or leave home. The mother blamed her overprotectiveness on her husband's hostility toward their son or her husband's inadequacies as a father. She claimed that her relationship with their son developed only after "trying" to get her husband involved as a parent. The father, in turn, blamed the mother for preventing their son from growing up by overprotecting him.

The fathers were of two general types. One could be termed the "straw-man type." This type was described as authoritarian or violent by other family members but was actually easily controlled by the mother. In one of the families interviewed, the "undeniable" evidence of the father's brutality was a vague incident that had taken place several years ago. In another family, evidence of a stepfather's explosive temper consisted of his wife's reports of harsh treatment of his own children.

The other type of father was also seen as distant from his family, but this type was more clearly secondary to the mother in terms of power within the family. As the brother of a 20-year-old addict stated, "My mother very early won us over . . . . Father sat out in the kitchen."

The father's attempts to control his son's behavior were always undercut by the mother. If the father had a drinking problem, which was frequently the case, he was even less able to take any action against his son's behavior. In several of the families in my sample, the fathers insisted that the addicts work and pay room and board as long as they were living at home. However, their sons remained at home unemployed and using drugs for as long as three years. Thus the addict's behavior was a constant reminder to the father of his weak position in the family.

Conflict between the addict and his father was reinforced by the father's secondary position in the mother's affections and his lack of authority in the household. This was perhaps best expressed by a barbiturate addict who said to his father about his mother, "You can have her back when I'm finished with her." Perhaps as a result of the alliance of mother and son against him, the father was much less involved with the family than the mother. Employment in several jobs often kept him almost totally removed from the family. The mother frequently verbalized her dissatisfaction with his noninvolvement with the family and blamed him for their son's problems, yet this conflict reinforced the father's noninvolvement.

The financial support provided by the father was his one source of gratification; at the same time it was an excuse to remove himself from family conflict. Most of the fathers in my sample had very low expectations of their sons' success. In general, they hoped their sons would find some kind of regular employment, no matter how menial. In fact, it has been stated (20) that fathers of drug addicts actively discourage their sons from striving to achieve success at their jobs.

Only two or three of the addicts in my sample were self-supporting; this support was usually contingent on their drug use. The rest were supported by either their wives, parents, or in-laws. The addict was in a position where the most significant male in his family said, "To be a man you have to work hard and make something of yourself," but his mother said, "You don't have to work because you are sick and can't." In addition, being a "real" man like his father did not appear to be an attractive goal.

The addict was generally seen as inadequate by other family members as well as by himself, his mother, and his father. For example, the twin brother of a 21-year-old addict stated, "Mom looked at you as the weak one. They made you weak." The sister of a 20-year-old addict said that her father told her brother on many occasions that he was not mature enough to go to college and that "nothing was expected of him." There was a consensus within these families that the addict was inadequate and needed help.

Parental Conflicts

The marital dyad in these families was characterized by emotional distance and a lack of interaction—except for those periods when the addict seemed to need the most help, i.e., when he was using drugs or his parents thought he was using drugs. The mutually accepted belief that the addict is unable to resist drugs functioned to make his parents interact, if only to argue about him. This kind of interaction created even more tension in the household, and the addict generally responded by increased drug use. One barbiturate addict in my sample stated that the only time he was able to enter into a dinnertime conversation with both his parents at the same time was after he had used drugs.

Problems in the parents' relationship were acted out through disagreements about the addict's drug use and his lack of employment. The mother generally verbalized her displeasure at her son's behavior but seldom really attempted to change it. Several addicts reported that their mothers found their heroin or their hypodermic needles and did not destroy them. Gibson (21) reported that the mothers of some addicts force their sons to leave home when they are not using drugs but encourage them to live at home when they are using them. One of my patients, a heroin addict, told me that some mothers leave money around for their sons to steal in order to buy drugs.

As a result of the familial conflict focused on his behavior, the addict saw himself as powerless and at the same time to blame for the problems between his parents. He was drawn into the conflict by supporting his mother or being attacked by his father and being supported by his mother, which reinforced the conflict between the parents.[2] This eventually caused the addict to withdraw from any interaction at home or to seek relief away from home. Either behavior made the mother even more anxious because withdrawal from the family indicated he was unhappy and more likely to use drugs. Her anxiety communicated to the addict that she felt he could not resist drugs.

In the attempt to "convince" the addict not to use drugs the parents inevitably disagreed as to what steps should be taken to stop his drug use; this caused even more tension within the parental dyad. The addict's drug use therefore continued, and everyone in the family felt helpless to solve the problem, particularly the addict. He learned that he could not really stop and that his family could not help him stop. He was not presented with any real alternatives because he was seen as being unable to resist drugs.

The belief that the addict is unable to control his drug use and therefore needs help reinforced the close relationship between the addict and his mother. However, another belief about heroin, that it reduces sexual interest,[3] was perhaps necessary to reduce the incestuous fears of the addict. The need for heterosexual activity with other women, which might have been anxiety producing because of the addict's low self-esteem, was eliminated by this belief. In my sample, all of the addicts stated that they had little sexual interest when addicted. At least half of them verbalized fears about heterosexual relationships and whether they could perform adequately sexually.

[2]The special relationship between the addict and his mother frequently created hostility between the addict and his siblings, who resented the special treatment given him.

[3]This does not appear to be part of the mythology of the barbiturates.

CONCLUSIONS

The addicts in this sample had inadequately separated from their families because of certain aspects of their parents' relationship. Their mothers' most intimate relationship was with the addict, whom they overprotected and infantilized in an effort to maintain the relationship. The addict's view of himself as unable to abstain from drugs reinforced what he and his mother felt to be the necessity to take care of him. As a result, the addict was unprepared for adult responsibility, and his addiction was a "legitimate" means of absolving himself from it. The mother was then able to "legitimately" take care of him. Thus as long as he remained addicted he would be taken care of by his mother. This alleviated his guilt about the anxiety he created in his mother when he attempted to separate.

The addict's relationship with his mother also exacerbated the distance between the addict and his father, whom the addict had replaced in the mother's affections. The mother defended the addict against his father, which created constant conflict between the parents revolving around the addict. Each parent blamed the other for the addict's condition; the addiction was a constant reminder that they were failures as parents.

At the same time the addict was able to maintain at least some relationship between his parents by his continued drug use. The father was drawn back into the family enough to fight with his wife about the addict and to blame her for the problem. Attempts on the part of the addict to leave caused anxiety in the addict and his mother, as did his remaining in the household; there was perpetual conflict whether the addict stayed at home or not.

The addict was caught in a paradox. He had been taught that to be a man one must work, but at the same time he was covertly encouraged to remain at home unemployed as long as he used drugs. Within the family much of the interaction focused on trying to "convince" the addict not to use drugs, which implied that he had some control over his drug-related behavior. At the same time, all family members viewed the addict as incapable of resisting drugs. The result was that the addict continued to use drugs. This was reinforced by his social interaction outside the family, which was primarily among drug users or people involved with drugs. The relationships outside the family were generally nonintimate and transient.

The addict's concern with drugs eliminated almost all extraneous stimuli. As Stephens and Levine (22) stated, the subculture provides the addict with a set of norms and a way of life. This was reinforced in the families in my sample, in which the addict's parents told him that he could not resist using drugs if he was with drug users. As a result, if the addict was with friends who were addicts, he would most likely continue to use drugs.

A Teaching Drill in Child Psychiatry

BY RITA R. ROGERS, M.D., AND BEATRICE RASOF, PH.D.

The authors report on a teaching drill for psychiatric trainees that tests their ability to communicate child psychiatry concepts to a nonpsychiatric physician and to parents of a disturbed child as well as their abilities in the role of a supervisor and a "visiting professor." It was found that the drill was a learning experience for the trainees that focused attention on their problems in integrating their psychiatric skills and identity with their identification with the medical model.

ONE OF THE MOST DIFFICULT tasks in educating psychiatric residents is that of integrating their acquired psychotherapeutic skills and psychodynamic understanding with their identity, knowledge, and skills as physicians. As the young psychiatrist becomes more skilled in conducting nondirective interviews and as his own behavior and responses to patients become reliable tools in his specialty, he may experience disdain for the recently acquired tools of a physician and feel inclined to dismiss them.

The medical style of history taking and recording appears to be an unnecessary responsibility; the idea of diagnostic categories seems rigid and meaningless, a way of forcing personalities into boxes. The psychiatrist in training who uses himself as a medical diagnostic tool feels restrained by medical "rigidities"; in his haste to develop the psychiatric "artistic" identity he becomes sloppy and negligent in his medical scientific inquiry. He seems to avoid committing himself to diagnosis, prognosis, and recommendation.

In response to this a teaching drill was designed for and practiced with psychiatric residents to help them bridge their identities as child psychiatrists and as physicians operating within the medical model.

THE TEACHING DRILL

Five groups of two students each were established for supervision: two second-year fellows in child psychiatry, two first-year fellows in child psychiatry, two third-year general psychiatry residents taking their elective in child psychiatry, two third-year residents in the required program, and two second-year general psychiatry residents rotating in child psychiatry.

The supervision drill took an hour and a half with each group. Its format consisted of one resident's giving a 10- to 15-minute report to the supervisor on a child whom he had evaluated during the preceding week and on the child's parents. He was required to give his report as if his supervisor were a nonpsychiatric medical referral source (the referring physician), emphasizing concise, pertinent findings about the parent-child relationship. The primary purpose here was to establish a therapeutic alliance with the referring physician, to thank him for his referral, and to inform him about findings and objectives. Special emphasis was placed on translating the psychiatric point of view into acceptable medical norms, standards, and styles for the nonpsychiatric physician. For example, a 13-year-old's request to be placed in a juvenile hall was translated as his attempt to signal his fear of losing self-control.

In the second part of the drill the resident conducted an interpretation interview with the child's parents. This interview took 30 minutes and was conducted in the presence of the supervisor and the other resident in the group (the resident observer). The first resident conveyed his impression of the child to the parents by asking for their view of the child and his behavior. Emphasis was placed on questions like "Why do you think he steals only from you?" and "How did you feel about his tic subsiding while he was in the hospital?"

Although the interview was conducted in the open-ended style of a diagnostic or therapeutic session, the parents were told what the child suffered from, how parent-child communication functioned, and what the recommendation for treatment was. The resident also told the parents who the primary patient was, which parent needed treatment and why, and what psychotherapy was.

In the third part of the drill the resident observer gave a 10-minute discussion of his colleague's interviewing technique. He asked questions about the style of interviewing and assessed his colleague's use of himself in interviews. (This part of the drill seemed valuable in training residents to be future supervisors and teachers. Further, it seemed to increase acceptance of supervision and foster cooperation and identification with the staff supervisor.)

Finally, the resident who had interviewed the parents of the child discussed the dynamics of the case in psychiatric terms with his supervisor and the resident observer. He was instructed to discuss his case as if he were a visiting professor attending a psychiatric conference where a patient had been presented to him. Here the drill emphasized articulation, clarity, knowledge of the literature, and professionalism as a psychiatrist.

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

The authors are with the University of California, Los Angeles, where Dr. Rogers is Associate Clinical Professor of Psychiatry and Dr. Rasof is Assistant Clinical Professor of Medical Psychology. They are also with Harbor General Hospital, 1000 W. Carson St., Torrance, Calif. 90509, where Dr. Rogers is Chief, Division of Child Psychiatry, and Dr. Rasof is Clinical Psychologist.

GENERAL FINDINGS

All of the residents were reluctant at first to commit themselves to an exercise in psychiatric training; they thought it was infantilizing at this advanced stage of their education.

They thought it premature and superficial to commit themselves to diagnosis, prognosis, and a definite course of treatment after knowing patients only a short time (one week). They were especially reluctant to offer a diagnosis and prognosis to a nonpsychiatric referral source. In short, they felt confined in their psychiatric breadth by the "stilted" medical model.

Their talents as psychiatrists varied—especially their abilities to do several things simultaneously. They had to report to a referral source and at the same time subtly convey mental health principles to a nonpsychiatric physician. They had to conduct an open-ended interview with parents and at the same time interpret for them their view of the child and the sources of this view. They had to express psychodynamic formulations with clear-cut delineations of what they knew, thought, and felt about the case.

The residents' therapeutic skills were particularly taxed in their efforts to establish a therapeutic alliance with a referring physician while subtly linking him to the psychiatric point of view. They also had to establish a therapeutic alliance with parents while making them aware of the emotional sources of their views of their children.

In general, cooperation was strongly influenced by the resident's feelings toward the supervisor (R.R.R.), who was chief of the child psychiatry division.

METHOD OF ANALYSIS

In order to measure quantitatively the usefulness of the teaching drill, six questionnaires were designed.[1] Questionnaire 1, filled out by the supervisor, measures the trainee's performance as a physician reporting his findings to a nonpsychiatric referral source (the role-play situation). Questionnaire 2, filled out by the supervisor, measures the trainee's ability to translate psychiatric findings to parents. Questionnaire 3, filled out by the child's parents, measures their impressions of whether or not they received a clear and empathically translated diagnosis. Questionnaire 4, filled out by the supervisor, measures the resident observer's ability as a supervisor. Questionnaire 5, filled out by the resident observer and the supervisor, evaluates the trainee as a "visiting professor." Questionnaire 6, filled out by the trainee, evaluates the teaching drill itself.

These questionnaires were used from November 19, 1973, to March 4, 1974. They measured findings on 29 patients (a total of 261 questionnaires). The sample of 10 trainees and 29 teaching drills that is reported here (see appendix 1) is an attempt to tabulate our findings and to measure the efficiency of the drill by means of data analysis. This is only a pilot study; the drill is continuing.

[1] These questionnaires are available from the authors on request.

RESULTS

The data selected for discussion were examined in a number of ways within the limits imposed by the sample and time. We confine ourselves here to a descriptive treatment of the findings representing the areas measured by the six questionnaires. Tables 1 through 6 give the proportions of positive responses or proportions of ratings in the upper half of the distribution in each of the six areas. Particular variables of interest were selected for more refined analysis.

Role Play with Referral Source

As shown in table 1, all of the psychiatrists in training tested were able to tactfully convey information to a referral source, discuss the patient's symptoms and their meaning, and give treatment recommendations with a degree of clarity in the upper half of the rating-scale distribution.

The weakest areas of performance were in giving a diagnosis, making a therapeutic alliance, and conveying mental health concepts. Not one individual discussed prognosis. Nevertheless, considering the transaction as a whole, the group was rated in the upper half of the rating scale in 21 of 24 instances; the median rating was 2.5 (a rating of 1 was highest, 6 lowest). The advanced child fellows did significantly better than the combined group of second- and third-year residents in giving a diagnosis ($p = .0064$, Fisher's exact probability test).

Interpretation Interview with the Parents

As seen in table 2, treatment recommendations were made to the parent of the patient in fully 90.9 percent of the cases; the degree of empathetic understanding shown was rated as above the median rating for 78.3 percent of the residents. The rationale for treatment was not given as often; in more than one-third of the cases the combined group of residents and fellows were not able to effectively translate the child's problems into language the parent could understand. A diagnosis was given in only 45.5 percent of the interviews and with only a moderate degree of clarity (median = 3). In very few cases was the meaning of psychotherapy explained. In no instance was prognosis discussed.

Almost three-fourths of the interviews conducted were rated in the upper half of the distribution (median = 2). A comparison of the effectiveness of the transaction as a whole conducted by child fellows compared with the second- and third-year residents indicated a difference in favor of the fellows at a lower level of confidence than in the role-play situation ($p = .13$, Fisher's exact probability test). A more representative sample might be expected to confirm the greater proficiency of the more highly trained psychiatrists who have chosen child psychiatry as a specialty.

TABLE 1
Frequency Distribution of Role-Play Interview Evaluations, in Percents

Variable	Proportion of Positive Responses	Proportion of Ratings in Upper Half of Distribution
Psychiatric information about the child translated into acceptable medical norms	55.0	
Symptoms and their meaning discussed	84.0	
Diagnosis given	52.2	
Treatment recommendations made	77.3	
Prognosis given	00.0	
Therapeutic alliance with referral source made	54.2	
Mental health concepts conveyed	66.7	
Clarity with which symptoms and meaning discussed		95.4
Clarity with which diagnosis given		100.0
Clarity with which recommendations made		82.4
Tact with which mental health concepts conveyed		100.0
Evaluation of transaction as a whole (understandable language as opposed to jargon)		87.5

TABLE 2
Frequency Distribution of Interpretation Interview Evaluations, in Percents

Variable	Proportion of Positive Responses	Proportion of Ratings in Upper Half of Distribution
Translation of information about the child's problem into language the parent can understand	65.2	
Discussion of symptoms and their meaning	47.2	
Diagnosis given	45.5	
Treatment recommendations made	90.9	
Rationale for treatment given	61.9	
Modality of treatment given	73.9	
Primary patient identified	65.2	
Parent in need of treatment identified and reason stated	81.9	
Explanation given of what psychotherapy is	23.8	
Prognosis given in terms parent can understand	0.0	
Clarity with which symptoms discussed		100.0
Clarity with which diagnosis given		100.0
Clarity of treatment recommendations		92.3
Completeness of recommendations (overall rating)		60.9
Empathic understanding and communication shown		78.3
Overall effectiveness of interview		73.9

TABLE 3
Frequency Distribution of Evaluation of Resident Observer as Supervisor, in Percents

Variable	Proportion of Positive Responses	Proportion of Ratings in Upper Half of Distribution
Appreciation of difficulties encountered by interviewer	81.3	
Understanding of interactional process between interviewer and patient	81.1	
Resident has ability to provide alternative ways of handling difficulties encountered	56.2	
Resident contributes over and above what staff supervisor contributes	50.0	
During role play	56.2	
During interpretation interview	62.5	
During "visiting professor" role	56.2	
Sensitivity to the interviewer shown		87.5
Clarity in communicating understanding of the interactional process		100.0
Overall evaluation of resident observer as supervisor		62.5

Of particular interest is the finding of no significant difference between the median rating of the favorableness of the interpretation interview given by the trainee when compared with that given by the supervisor.

Resident Supervisor Interview

As shown in table 3, the resident observers in the role of supervisor were to a high degree sensitive and appreciative of the difficulties encountered by their fellow trainee in the interpretation interview. The resident supervisors were usually able to understand the interactional process between parent and interviewer and to convey this clearly. To a lesser extent they were able to provide alternate ways of dealing with problems that arose during the interview. In from 50 to 60 percent of the interviews or role-play situations the resident supervisor was able to contribute ideas over and above those provided by the staff supervisor.

A highly significant difference between the residents and child fellows was noted in comparisons of their overall evaluations as a supervisor. The null hypothesis that the proportion of trainees with ratings 1–3 and ratings 4–6 in the supervisory role was equal for residents and child fellows was rejected ($p=.0003$, Fisher's exact probability test).

Evaluation as "Visiting Professor"

As shown in table 4, there appeared to be less variability in this section of the drill. All trainee psychiatrists

TABLE 4
Frequency Distribution of Evaluations of Trainee as "Visiting Professor," in Percents

Variable	Proportion of Positive Responses	Proportion of Ratings in Upper Half of Distribution
Psychiatric information about the case translated into suitable conceptual framework	85.0	
Knowledge of the literature incorporated in meaningful way	5.0	
Clarity with which psychiatric information communicated		100.0
Articulation with which psychiatric information communicated		100.0
Professionalism shown		100.0

who were able to translate psychiatric information about a case into suitable conceptual terms did so with a very high level of clarity and articulation (median rating = 1.0). In striking contrast, only 5 percent incorporated knowledge of the literature in a meaningful way into the case discussion.

Parent Interview Survey

As shown in table 5, the parents reacted favorably to the interview; 84.2 percent made judgments in the upper half of the rating scale (median = 1.5). The degree of understanding parents attained about their children after the interview was closer to the center (median = 3.0) but 90.5 percent felt they understood their children somewhat better or much better than before. Almost all of the parents also reported getting all the information they needed. The more prominent emotions checked on the list were feeling understood by the interviewer and feeling optimistic. Less than half of the parents (36.4 percent) reported feeling more anxious and 27.3 percent reported feeling less anxious than they had felt before the interview.

It is interesting to compare the parents' perception of the interpretation interview with that of the supervisor. In the sample of 19 cases, 8 individuals rated the interview as better and 7 as worse than did the supervisor; 4 rated the interview the same. Thus the median of the ratings made by the parents did not differ significantly from the median of the ratings made by the supervisor at usual levels of significance using the sign test. Equally interesting was the finding of no significant difference between the median self-rating of the trainee and the median rating of the supervisor.

Evaluation of the Teaching Drill

As shown in table 6, the evaluation of the drill by the participating residents and fellows indicated that in 78.1

TABLE 5
Frequency Distribution of Parents' Evaluations, in Percents

Variable	Proportion of Positive Responses	Proportion of Ratings in Upper Half of Distribution
Overall reaction to interview		84.2
Understanding of child's problem after interview		90.5
Desired information discussed	90.9	
Recommendations and steps to be followed presented clearly	90.9	
Feelings during or after interview		
Pessimistic	18.2	
Angry		
At therapist	13.6	
At child	0.0	
At self	4.5	
At others	4.5	
Optimistic	45.5	
Ashamed	9.0	
Disappointed	9.0	
More anxious than before coming to clinic	36.4	
Less anxious than before coming to clinic	27.3	
Misunderstood by interviewer	13.6	
Understood by interviewer	81.9

Descriptions of drill		
Impractical	2.8	
Artificial	0.0	
Stimulating	62.9	
Well conducted	74.4	
Forced one to think more clearly about patient's dynamics	68.6	
Clarified perceptions and misperceptions about ongoing interactions	65.7	
Feeling during or after drill		
Angry	8.6	
"Put down"	0.0	
Stupid	5.7	
Satisfied	62.9	
Had done a good job	17.1	
Other*	—	
Retain teaching drill as it is	78.1	
Comparison of drill to one-to-one supervision		77.2
Attitude to role-play supervision		88.2
Sensitivity of supervisor to training needs		91.5
Feeling of openness in discussing interview with supervisor		91.5
Better understanding of how to integrate theory and case studies from literature		78.1

*The open-ended replies were not tabulated.

percent of the sessions rated they would retain the entire teaching drill as it is. An almost equal proportion felt that what was learned by this method could not be as readily learned in the usual one-to-one supervision. The role-playing situations were found valuable in 88.2 percent of the interviews. Particularly high was the rating of feeling of openness in discussing the interview with the supervisor. Sensitivity to the learning needs of the trainee was rated equally high. A large number of the drills were found to be stimulating, well conducted, and successful in forcing the trainee to think clearly about the patient's dynamics and in clarifying perceptions and misperceptions about ongoing interactions. None of the trainees found the drill to be artificial, and in only one instance was the drill considered impractical. In the majority of the sessions, the trainees felt that they had attained a better understanding in integrating theory and case studies from the literature into their style of reporting to a referral source or seminar.

The Clinician-Supervisor as "Computer"

There was some satisfaction in the finding that the overall clinical judgment of the rank order of the trainees' performance made at the end of the study by the supervisor was significantly related to the rank order based on an average of the ratings made at the time of the drill sessions (rank correlation of .78, $p = .01$, $N = 10$).

USES OF THE DRILL

While the drill seemed a valuable exercise for future practitioners, teachers, and supervisors, its primary aim was to link the residents' psychiatric and medical identities, which appeared far apart.

The results show that the psychiatric trainee is indeed accomplished in understanding and conveying clinical data but that he has a definite disinclination toward committing himself to a diagnostic framework and completely avoids voicing a prognosis, in spite of the repeated filling out of questionnaires that included the category of prognosis. Both the avoidance of diagnostic formulation and resistance to uttering a prognosis seem related to the psychiatrist's estrangement from the medical model. The psychiatric trainee almost always recommended treatment although he had not given a prognosis in the role-play situation and had given a diagnosis to the parents in only 45.5 percent of the interviews.

The trainee seems to identify himself primarily as a psychotherapist, but he finds it difficult to clarify what psychotherapy is. He does not feel a responsibility to define to the parents what ails the child and how he will treat the difficulty.

In the role of supervisor the trainees showed a high degree of sensitivity toward their colleagues' difficulties but a limited ability to provide alternative ways of handling them. (This is probably due to uncertainty and inexperience in the role of supervisor; all the trainees have been recipients of supervision, but few have had the opportunity to supervise.)

The drill did not increase the trainees' responsibility toward the medical model of diagnosis and prognosis. It only brought their avoidance into focus and highlighted the need to search for the causes of this avoidance both in the training program and in the trainees' identity as psychiatrists.

The drill did help the trainees in other areas, however. They became more skilled and articulate as they gained confidence in their abilities to translate findings from one mode to another—from the medical language used in their reports to the nonpsychiatric physician to the therapeutic language appropriate to the emotional milieu of the parents to the didactic language appropriate to psychiatric conferences.

The trainees' ability to fulfill the different roles required of them depended on their security as people and as psychiatrists, on their relationship with their supervisor, and to some extent on the nonambivalence of the psychiatrists who had been important models during their entire psychiatric training.

The supervisor (R.R.R.) found that the drill provided an invaluable glimpse of the psychiatrist in training. She found her greatest reward in the opportunity to see some of her trainees' skill and ease in functioning as accomplished psychiatrists as they faced the tasks of understanding and being understood by their patients.

APPENDIX 1

Explanation of the Sample

The data reported in this paper cover the period of time from November 19, 1973, through March 4, 1974. The sample size reported in the tables is sharply reduced by the decision to use only those ratings made by one supervising staff person (R.R.R.). Twenty-three drills in which the patient was present and in which the interview was carried out by the trainee were conducted by Dr. Rogers.

In one session Dr. Rogers conducted the interpretation interview at the request of the trainee. Child fellows supervised the others while Dr. Rogers was absent. The trainee participated both as an observer and as a resident supervisor, along with the major therapist. The number of different patients interviewed by each trainee is the variable factor. Two trainees participated in 5 and 6 drill sessions respectively, 4 conducted 3 each, 2 conducted 2 sessions, and 2 conducted 1 each for a total of 29 teaching drills carried out by 10 trainees.

DISCUSSION

ROBERT E. SWITZER, M.D. (Topeka, Kans.)—I am grateful to Dr. Rogers and Dr. Rasof for this description of their innovative system for judging how child psychiatry fellows and general residents in psychiatry are able to bridge their identities as physicians and as specialists in child psychiatry. This drill asks the trainees to do a very difficult thing: to look at their own performance. They are asked to open themselves up to the scrutiny of a peer as well as the scrutiny of a teacher and to do it in terms of role playing.

If the trainee does not already have plenty of doubts about

his findings, his formulations, his diagnosis, and his recommendations, not to mention prognosis, the thought of reporting back to a nonpsychiatric referral source after having seen his patient for only one week is bound to put him on the defensive and to cause some struggle in terms of his identity as a physician and as a psychiatrist. I can identify with the trainee's struggle in not wanting to commit himself. I well remember my days as a first-year resident; we all wanted to wait for the psychological report before we really committed ourselves. I think the first part of this drill is excellent and I see it as applying rigor rather than infantilization.

The second part of the drill, which calls for interpreting the child's problems to his parents, gets a little more complicated. Many residents would certainly see this sort of experience as infantilizing and very threatening. Only great skill on the part of the supervisor and repeated experiences could make this part of the drill a very positive and growth-promoting experience. It seems to me that I have known some supervisors who might never rise to this occasion.

I think the third part of the drill, in which the resident observer takes the role of supervisor, is excellent. I have used twin supervision of residents in diagnostics as well as in psychotherapy for a long time. It seems to me that it may be useful when assigning the two residents to take this drill to let the residents participate in choosing their drill mates. I agree with Drs. Rogers and Rasof that this part of the drill is a good way to teach a young clinician some supervisory techniques.

In the fourth part of the drill the resident can allow himself to assume the senior visiting clinician's role after having explained to a referral source and to parents his findings and thoughts about the case. This part of the drill may be a little stilted. I shared this paper with a third-year resident who thought that the paper was fine and that he would like to participate in such drills. However, he had a criticism of the fourth part of the drill. He thought that it assumed a visiting professor had to be pompous and verbose and had to say things in a different way than he would to a referring physician or a troubled parent. He thought that the really secure physician-psychiatrist would not be too different in any of the three roles outlined in the drill.

The authors found a tremendous variety in the performance of the residents according to their level of sophistication in child psychiatry. I would think that there would also be tremendous differences between the residents who came into psychiatry right out of medical school without an internship compared with those who had had long periods of private general practice or military or Public Health Service duty. I would also predict, as Drs. Rogers and Rasof found, that a great deal of the resident's performance would be related to his relationships with his supervisor and with his peers.

It would seem logical to assume that second-year residents in general psychiatry would have much more difficulty with this drill because of their short experience in dealing with children and their parents when compared with second-year fellows in child psychiatry. In addition to having had considerably more experience the fellows also probably had the advantage of having worked with this supervisor for at least a year before the drill. In that sense the drill and its documentation could well be taken as a test of training, i.e., a second-year fellow who does much better in this drill than he did as a first-year fellow might be said to have profited by his second year and to have become more efficient in the skills taught. In another sense the drill could be used to select residents who might be urged to go into child psychiatry.

This paper represents the first complete sampling of the drill and its questionnaires. It may be that the data have not yet been analyzed well enough to answer all of our questions. I had one thought about prognosis. It would seem to me that the finding about the trainees' failure to give parents a prognosis would persist. It has been my observation that trainees have great difficulty with their inability to talk definitely about prognosis. I would really wonder about a fellow who spontaneously got into a discussion of prognosis.

Sexual Dysfunction in College Men and Women

BY ARNOLD WERNER, M.D.

The author presents data and illustrative excerpts from 1,000 letters relating to health and personal concerns that were sent to his column in a college newspaper. There were 532 letters expressing sexual concerns, 65 percent of which raised questions about anatomy and physiology. A comparison of the distribution of problems of sexual dysfunction in this study with that of an earlier study involving older patients showed very different distributions. The author points out the need for sex counseling and education for young people who are sexually active and discusses the unique problems involved in treating this population.

THE LARGE INCREASE in the amount of sexually oriented material presented to the public suggests that there is now a greater openness about sexual matters in this country than has existed in the past. Explicit motion pictures, illustrated magazines, and books abound. In addition, instructional manuals and digests of sex research with the ostensible goal of improving the reader's sexual capabilities are sold widely. Many colleges offer courses in human sexuality, and sex counseling services are becoming available on college campuses (1).

With increased sexual awareness, people may be less willing to accept sexual dysfunction than they were in the past, and adequate sexual performance may become part of their definition of a complete life. It is certainly true that interest in sexual functioning is no longer considered too private to discuss or too deviant to acknowledge.

Revised version of a paper presented at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

The author is Associate Professor of Psychiatry and Director of Psychiatric Services, University Health Center, Michigan State University, East Lansing, Mich. 48824.

This work was supported in part by grant RR-05656 from the General Research Support Branch, Division of Research Facilities and Resources, National Institutes of Health.

The author is indebted to Ms. Carol Keating and Ms. April Lochner for their assistance in various aspects of this study. Ms. Lochner worked with the author under grant MH-11720 from the National Institute of Mental Health.

A NEW SOURCE OF INFORMATION ABOUT HEALTH AND PERSONAL CONCERNS

The clinician's knowledge of people's frailties usually comes from his patients. The hazards of generalizing our observations of such a highly selected group are well known, yet there are few opportunities for gathering information from any other source. Information about the sexual activities and concerns of college students is particularly difficult to obtain.

Because of an ongoing project of more than four years' duration, I have been in a unique position to gather information about the health and personal concerns of college students. With the development of psychiatric services at the Michigan State University Health Center, I began to write a weekly column dealing with these concerns for a student newpaper. The paper, which is published daily, has a circulation of 40,000 and is the prime source of news for most of the student body. In addition, it has a wide readership in the community. The goal of my column, which is called "The Doctor's Bag," is to provide a service to the university and to promote attitudes and offer dispositions consonant with the aims of college and community mental health.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editors consider this material to constitute a comprehensive analysis of the topic.

By offering myself as a free, confidential source of information, I became the recipient of many hundreds of letters from students seeking advice and answers to personal questions. In addition to publishing students' letters and answers to their queries, I tried to answer all the letters that were not published as long as the writer was identified.

The column provides rich personal accounts of health and other concerns. Unlike other data, which are often anecdotal, i.e., obtained from patients and/or structured, preestablished survey instruments, the material I obtained dealt with the private concerns of students. The categories, formulations, and centrality of these concerns were structured by the students themselves. Although the column appears in about 50 college newspapers, the material for this study was all derived from Michigan State University students.

ANALYSIS OF STUDENTS' CONCERNS

Content analysis of 1,000 consecutively received letters revealed that 52 percent contained sexual questions, which confirms the generally held impression that college students have many questions about sex. As table 1 shows, the questions often revealed a striking naïveté and lack of information: 65 percent of the sexual questions related to basic physiology and anatomy, the mechanics of contraception, and venereal disease. The other 35 percent were concerned with sexual activity. Over 30 percent of the questions relating to sexual activity dealt with sexual dysfunction. (These letters represented 5.6 percent of the total sample of 1,000 letters.)

These 56 letters were categorized on the basis of whether the problem was primarily a woman's or a man's concern. Within each category, I followed the definitions of dysfunction used by Masters and Johnson (2) whenever possible. All judgments about dysfunction were based on statements in the letters rather than my own inferences. This categorization is presented in table 2.

TABLE 1
Breakdown of Concerns Expressed in 1,000 Letters from College Students

Type of Question	Number	Percent*
Sexual questions (N=523)		
Anatomy and physiology	340	65
Venereal disease	22	7
Contraception	99	29
Female anatomy	151	44
Male anatomy	68	20
Sexual activity	183	35
Sexual intercourse**	104	56
Oral and anal	32	17
Petting	26	14
Masturbation	18	10
Homosexuality	3	2
Nonsexual questions (N=477)		
General health	202	42
Medical	186	39
Psychological	46	10
Drugs	43	9

*Percentages within each classification are based on the total number for that category alone.
**Includes all questions related to sexual dysfunction.

TABLE 2
*Breakdown of the 56 Questions Related to Sexual Dysfunction**

Type of Question	Number	Percent**
Questions related to men's problems (N=27)		
Premature ejaculation	16	59
Impotence	6	22
Primary	3	50
Secondary	3	50
Ejaculatory incompetence	1	4
Other	4	15
Questions related to women's problems (N=32)		
Orgasmic dysfunction	24	75
Primary	8	33
Situational	16	67
Other concerns	8	25
Painful intercourse	4	50
Low sexual interest	2	25
Other	2	25

*Three letters were classified as related to both men's and women's problems since the writer wrote of a mutual concern.
** Percentages within each classification are based on the total for that category alone.

CONCERNS RELATED TO SEXUAL DYSFUNCTION

Women's Problems

The problems of women cause distress to their partners, and 6 of the 32 letters relating to female sexual dysfunction were written by men. However, in each case, the man saw the problem as being solely the woman's concern rather than a joint problem. There were four letters about painful intercourse. The three involving pain with penetration were written by men. There were three letters describing situations in which the woman suffered from orgasmic impairment and the man had premature ejaculation, all of which were written by women.

The bulk of concerns related to female sexual dysfunction clearly involved orgasmic impairment. These problems covered a considerable range. One woman wrote, "My fiancé is able to reach a climax even though I cannot. While I love him I do not enjoy intercourse, but I feel I should engage in it for his sake." The female partner of a married couple wrote, "I am no longer interested in sex. I have no drive and it takes quite a bit of stimulation to get me the least bit interested." She then described the onset of the difficulty following several urinary tract and vaginal infections and stated that she was concerned that

her marriage would eventually be jeopardized. Complaints concerning coital orgasmic dysfunction usually indicated that orgasm was possible with manual stimulation either before or after intercourse.

Since the population studied consists of young adults, some of the problems in the letters had a particularly youthful quality, often tinged with lack of experience or knowledge. The following excerpt is an illustration:

> I am 20 years old. My boyfriend and I have been having intercourse for a year now, but only on weekends since he goes to another school. I have never had an orgasm from intercourse alone. I have had orgasms as a result of clitoral stimulation during masturbation. My boyfriend never touches my clitoris. Is there something wrong with me? Am I undersexed?

Another coed wrote that she had learned in a human sexuality course that women are capable of multiple orgasms but that she herself was not.

> During intercourse my boyfriend is able to achieve more than one orgasm whereas I am only able to achieve one. I am very satisfied and fulfilled after having intercourse but can't help but feel that I should be able to have more than just one orgasm. What is wrong with me?

There are glimpses in the letters of the beginning of sexual problems that will undoubtedly persist. Often, these women were aware of the threat to their future happiness.

> We have been making love for two years and will be getting married in about one year. This is great. The problem is that I am not very interested in sex . . . I have never come close to an orgasm. Lately, it sort of panics me—here is a man I'll be living with for decades, and I can't even respond to him.

An older student presented a situation of a similar nature that was further along the continuum of distress.

> During our marriage I have never climaxed with intercourse, only manually on occasion. I have little enthusiasm for sex, and this coupled with my husband's frustration at not being able to satisfy me has sadly corroded our marriage. For many reasons, including children, we do not want a divorce; neither do we look forward to continuing the situation.

While there were no complaints about inability to reach orgasm by masturbation, several women were concerned because they could only achieve orgasm during sexual intercourse in certain positions, usually the female superior position. Included in the group of women who had situational orgasmic dysfunction are those who at one time had no difficulty but currently were troubled. A few of these women gave histories in which the use of oral contraceptives was coincident with diminished sexual response. Others wrote of success with a previous partner but failure with a current partner.

Twelve correspondents in this group asked for referral to a treatment source. Some had previously had difficulties in their attempts to seek help. In some cases, the difficulty was related to the writer's single status and to the insensitivity they perceived in traditional care givers. One writer simply asked, "Do you know of anyone who counsels people who are not married?"

All of the letters related to female sexual dysfunction communicated considerable distress and disruption. There were no idle inquiries prompted by curiosity, as is often the case in letters I receive that deal with other health concerns.

Dysfunction In Men

Table 2 also presents a breakdown of the 27 inquiries about male sexual dysfunction. It should be noted that three problems have been classified in both this group and the female group because the writer so clearly identified the dysfunction as a mutual problem. These three letters were those written by women with orgasmic dysfunction who had partners with premature ejaculation. Another fact worthy of note is that all of the letters in the male dysfunction category written by women concerned premature ejaculation rather than impotence.

Premature ejaculation was the largest single source of concern in all of these letters. Some of the situations described were quite explainable and relatively benign. One such letter included the following:

> During sexual encounters I seem to reach orgasm very fast, always having at least one before intercourse begins . . . They even occur at odd times as when I was giving my girl a back massage. Could it be related to the fact that I never see my girl more than once a month and always feel a high degree of excitement when I do?

In some ways, this quote typifies the problems of younger people who are sexually active. These couples maintained high expectations, even though they had intercourse on an irregular basis under circumstances that were often rushed or awkward. The goal of helping people achieve good sexual functioning under such circumstances is complicated.

Many of the letters dealing with premature ejaculation indicated that this was an isolated concern in an otherwise satisfactory relationship, but there were times when the problem dominated interpersonal interactions. For example, a 21-year-old man wrote letters to me on two occasions separated by about 10 weeks. Describing himself as a shy person in his initial letter, he asked for advice in managing a situation that had developed in his first close relationship with a woman. He was alternately unable to get an adequate enough erection to achieve penetration or he ejaculated before entry. He perceived his girlfriend, who was understanding at first, as becoming less tolerant, and felt that the relationship was threatened. His second letter indicated that the relationship had ended. This was the only letter in which dysfunction was blamed for actual termination of a relationship, and the author clearly expressed self-doubts that extended beyond sexual performance.

The problem of primary impotence as an isolated entity appeared only twice in the letters. In one of these

cases, erection was repeatedly lost so quickly after entry that successful intercourse was never accomplished. The other case barely qualifies as a problem of primary impotence as it was a failure during a first attempt at intercourse with a virginal girlfriend. Advice and reassurance were requested by writers of these letters, who were distressed and puzzled. They often asked for an explanation of what was happening. Those who were impotent were more generous in postulating hypotheses for their disorder. They indicated that feelings of inferiority, inadequacy, lack of confidence, and unspecified psychological explanations might be pertinent. In a similar vein, three of the male correspondents expressed the fear of eventually becoming impotent, even though their letters provided no objective evidence that such fears were justified.

One case of ejaculatory incompetence emerged in a 19-year-old.

> I cannot ejaculate willfully. The only time I ejaculate is during sleep in the form of a wet dream. This bothers me greatly as I am unable to masturbate and cannot come, even when my girlfriend has oral sex with me.

DISCUSSION

The writers of letters to my column have typically been uninhibited in the questions and concerns they have raised. By answering virtually any type of health question in this public format, I have encouraged viewing all concerns as legitimate. While there is no way to ascertain accurately how representative these correspondents are of the entire student population, much valuable information can be derived from this nonpatient group.

Sexual dysfunction is a small concern in this group compared to all other health concerns (56 of 1,000 letters). The intensity of distress expressed in these 56 letters was quite great, exceeded only by the frightened individuals who were worried about an unwanted pregnancy. Among those individuals who raised questions about sexual activity, however, almost one-third dealt with dysfunction.

Table 3 presents a comparison of the 56 correspondents in my sample with concerns related to sexual dysfunction to 790 patients described by Masters and Johnson (2). The two populations are vastly different. Masters and Johnson's group consisted of highly selected patients who often had severe problems. They were also older, ranging from 23 years old to 76 years old. (Their youngest patient was probably older than the median age of my correspondents.) Because the groups are so different, the comparison is all the more interesting.

A much smaller percentage of woman in my study suffered from primary orgasmic dysfunction. Apparently, despite their inexperience, the young women in this study were having less difficulty having an orgasm at least one time than they were having orgasms regularly. The possibility is raised that younger middle-class women are having less difficulty in achieving initial sexual satisfaction than older women had. Considering the academic, financial, and social stresses young women are under, the finding that situational orgasmic dysfunction is a major concern should be no surprise.

TABLE 3
Comparison of Types of Sexual Dysfunction Reported in Two Studies, In Percents

Nature of Dysfunction	Masters and Johnson Study	Present Study
Female dysfunction	(N=342)	(N=24)
Primary orgasmic dysfunction	56	33
Situational orgasmic dysfunction	44	67
Male dysfunction	(N=448)	(N=23)
Primary impotence	7	13
Secondary impotence	48	13
Premature ejaculation	41	70
Ejaculatory incompetence	4	4

Premature ejaculation overwhelmingly dominates the other categories among the disorders of men. Rapid ejaculation is no detriment to reproduction and seems to be the usual case in the animal world (3) and among many men (4). It has been suggested that premature ejaculation in human males may be the result of early conditioning by prostitutes and other sexual contacts designed for self-gratification rather than gratification of a partner (2). The older men in the Masters and Johnson pool of patients had had substantial contact with prostitutes. Far fewer young men today seem to have initial sexual experiences with prostitutes than was true in the past (at least among college students I have contact with). In this population, premature ejaculation seems merely to be another expression of the hyperactive sexual status of the younger man (similar to his capacity for easy arousal and multiple orgasms) rather than a result of faulty conditioning. Active processes, including greater sexual experience and the reinforcement of delayed ejaculation as a good thing, lead sexually successful men to adapt a pattern of response that provides greater gratification for their partners. Aging undoubtedly helps in this process. Delaying response is actually a process of learning a new behavior or becoming deconditioned to what is natural. Unfortunately, the slow learner or especially hyperactive man may experience feelings of inadequacy.

Information about the nature of sexual response and instruction in sexual technique has been helpful to many of my correspondents and to others I have seen in consultation. However, immense problems are posed in treating people who are without regular sexual partners or who have sexual partners who are unable to cooperate in a treatment plan, situations that arise in a youthful population. The dilemma is clear. It is important that young people who are sexually active learn to function well if their hopes for good functioning in the future are to be realized. However, the conditions necessary for helping are often not present.

Lest I sound pessimistic, I should point out that I have been struck by the sensitivity and caring expressed

in letters sent to me by partners of individuals with sexual problems. There is often an openness and willingness to help that is almost astounding, and only one letter indicated dissolution of a relationship because of sexual difficulties.

Two recent articles have indicated that increased sexual freedom has created problems for some individuals (5, 6). A "new impotence" based on the demands of women for sexual gratification has even been suggested. The data I have presented do not support this suggestion. Not one case emerged in which the female partner was cited as the cause of a man's problems. The following excerpt from a letter summarizes the attitudes of the writers far better than my descriptions:

> My boyfriend and I have been dating for three years. We just started having sexual intercourse the past two months. Up until this time we petted to orgasm. The problem now is that my boyfriend has his orgasm almost as soon as he enters. He gets very upset and feels that I am getting nothing out of it. I want to be able to help him last longer—for both of us. I'm afraid if I can't, he'd be more satisfied and under less pressure to "perform" if we reverted back to petting. I would appreciate any advice so I could help him and our sexual relationship.

Before we attribute symptoms to current social mores, we might best acknowledge that there will always be individuals who function well and those who will function poorly. The manner in which the less able choose to present their inadequacies will always be in the language and mode of the time they live in, and this does not necessarily indicate anything about the frequency or prevalence of a condition. Furthermore, the interest of the helping person also reflects current trends and exerts an influence on the formulation of the problem. In this era of acknowledgement of the importance of adequate sexual functioning, we can expect more concerns about this aspect of human interaction to be voiced by both patients and clinicians.

DISCUSSION

D.K. KENTSMITH, M.D. (Omaha, Neb.)—Within the past 100 years, methods of obtaining information about human sexual behavior have been varied and often unique. These data collection methods have included case histories, questionnaires, interviews, self-reports, and direct observation.

The case history is a pathological approach in which a patient's history becomes a measure of what is abnormal. Freud, Havelock Ellis, and Krafft-Ebing were pioneers in the use of this method, and their case histories have been rich resources in understanding abnormal human sexual behavior. The major defect of this method is its lack of understanding of what is normal.

Some of the other methods have attempted to deal with this problem. The questionnaire, which was first used by Exner (1) in 1915 to obtain sexual information, is probably the least threatening and easiest to administer. The interview, either guided or unstructured, is a reliable and well-known technique. Beginning early in this century, Hirschfield (2) and then, later and more extensively, Kinsey and associates (3) used quite structured and well-designed interviews that provided some of the most complete and extensive studies in the area of human sexuality.

Probably the most reliable and accurate attempts to gather information on sexual behavior to date have been the classic physiological studies by Masters and Johnson, Fox and Fox (4), and Hellerstein and Friedman (5) using actual observation of sexual function in a normal group of people. The data collection methods I have described vary widely in their reliability and accuracy, with direct observation and measurement of physiological function being the most reliable.

The method Dr. Werner has chosen, voluntary self-report in letters to a newspaper column, must be viewed with caution, and any generalizations made must be limited to the group studied.

One must also be critical of Dr. Werner's definition of terms. It is difficult to see how Masters and Johnson's precise operational definitions of sexual dysfunction could be so easily abstracted from the students' letters, especially since this method does not afford the opportunity for even the simplest clarification.

However, if we can accept these technical problems, the findings of this study do add to our understanding of sexual functioning in a group of college students. Dr. Werner has added information supporting the hypothesis of an evolutionary survival value in premature ejaculation. His observations lend support to the theory that this neurophysiological phenomenon is an inherent, genetically programmed sequence of events rather than the result of faulty conditioning.

It is painfully apparent that an attempt to generalize Masters and Johnson's therapy technique is an acute need for young, single adults. Also, the large number of sexual concerns relating to physiology and anatomy expressed in the letters clearly illustrates that there is a continuing need for education in this area, despite our rather dramatically increased openness about sexuality.

One must be cautious in comparing the small number of women with sexual dysfunction in this study to the larger number studied by Masters and Johnson. However, the striking difference in the percentage of these women who experience situational orgasmic dysfunction raises several questions, such as whether there is increased peer pressure to experience orgasm in college women.

Dr. Werner has shown how an open and nonthreatening method can be used to obtain information on general and personal concerns. While the method has many sources of potential error, especially that of investigator bias, it does provide a general means of sampling the concerns expressed by a group of people.

Desensitization Therapy in Impotence and Frigidity: Review of the Literature and Report of a Case

BY BURTON S. GLICK, M.D.

The author reviews the available scientific literature on the use of behavior therapy in the treatment of impotence and frigidity, noting that there is a dearth of published information in this area. Behavioral techniques are described, and a case of impotence and anhedonia that responded well to relaxation/desensitization therapy is presented. The author concludes on the basis of his clinical experience and review of the literature that desensitization has definite value in the treatment of impotence and frigidity.

DESPITE THE RECENT burgeoning popularity of behavior therapy, published information on its use in treating the two most common sexual dysfunctions (impotence and frigidity) is sparse. A review of the literature in English revealed reports of only 13 cases of impotence and 33 cases of frigidity treated with behavioral techniques. This dearth of information is probably related to the intimate nature of the subject matter and to the influence of older analytic orthodoxies. This paper will present a summary review of the literature and a description of behavioral treatment in a case of impotence.

DESCRIPTION OF THE TECHNIQUE

Behaviorists believe that responses inimical to the development of anxiety will result in abolition of anxiety by either inhibition or extinction (probably the former). Consequently, there will be a loss of anxiety-rooted symptoms, and the individual will have an opportunity to learn or relearn healthy, adaptive patterns of behavior. Among these anxiety-inhibiting responses are the following:

1. Deep muscular relaxation. This can be achieved by specific training methods such as Jacobson's progressive relaxation (1), by hypnosis, or by drugs like intravenous sodium methohexital (Brevital).

2. Sexual responses. From the large repertoire of possible sexual activities, the therapist instructs the patient to perform only those activities which he/she desires and which are not likely to result in anxiety or failure.

3. General assertive responses. These responses include behaviors such as speaking up to one's boss, expressing counterviews firmly, or saying no to an unreasonable request.

Relaxation is an integral part of Wolpe's (2) method of systematic desensitization, also known as reciprocal inhibition. Although desensitization was originally designed specifically to treat phobias, it soon became apparent to Wolpe and others that the technique was also applicable to certain sexual disorders. These disorders may be considered phobic responses because they arise from anxiety.

Briefly, systematic desensitization involves presenting the patient, who is in a state of deep muscular relaxation, with a series of imaginary sexual scenes that he is to visualize as vividly as possible. Hypnosis may be used as an adjunct to achieve greater relaxation and more graphic visualization. The imagined scenes proceed gradually from the most innocuous (e.g., talking to a member of the opposite sex) through intermediate stages (engaging in various sexual preliminaries) to the most fearful (actual sexual intercourse). These graded scenes constitute the "phobic hierarchy." The patient immediately signals the

Dr. Glick is in private practice in New York City. Address reprint requests to him at 63 East 75th St., New York, N.Y. 10021.

therapist (usually by moving a hand or finger) if he experiences anxiety during the visualization. When this happens, a previous nonthreatening scene is presented, and the conditioning process resumes its hierarchical course. No scene may be introduced until the patient has visualized all prior scenes in the hierarchy without anxiety. Thus inhibition of the inappropriate, maladaptive neurotic reaction is presumably achieved and the patient is conditioned to respond with relaxation to stimuli that previously evoked anxiety. The expectation is that the patient's accomplishments in the therapeutic milieu will generalize to his real life.

BEHAVIORAL TREATMENT OF FRIGIDITY

The largest series of cases of frigidity treated with behavioral techniques was reported by Lazarus (3), who used relaxation and desensitization to treat 16 cases of "recalcitrant and persistent frigidity, many of which had failed to respond to the usual run of psychiatric techniques." His anxiety hierarchies depicted increasing degrees of sexual intimacy, as is customary in this technique. After a mean of 29 desensitization sessions, 9 of his 16 patients (56 percent) were regarded as sexually adjusted. Lazarus' standards for success were high, requiring that the patient almost always reach orgasm. Whenever possible, patients' husbands were interviewed separately and encouraged to express their opinions concerning the outcome and effect of therapy. Lazarus' follow-up inquiries strongly suggested the durability of the method, and he concluded that no other therapeutic approach could achieve comparable results in the treatment of chronic frigidity.

Madsen and Ullmann (4) used a variation of this technique in which the husband verbally presented the hierarchy items to his wife during therapy sessions. Only one of the seven women they treated had ever experienced orgasm by any technique. They used the relaxation/desensitization method and described their results as "generally favorable." However, with the exception of one case, the authors did not present either their criteria for success or the extent of their failure.

Brady (5) modified Wolpe's desensitization method by using subanesthetic doses of intravenous sodium methohexital to induce rapid, deep muscular relaxation and freedom from anxiety just before and during each therapy session. The patient's husband was also interviewed during the anamnesis, and the nature of the treatment was explained to the couple. Brady obtained "marked improvement" in four out of five cases of severe chronic frigidity in a mean of 11 sessions. The patient's sexual adjustment at the end of treatment was corroborated, if possible, by an interview with her husband.

Brady's criteria for marked improvement were fairly stringent and included pleasurable sexual activity, without anxiety, that culminated in orgasm at least some of the time. Follow-up of the improved patients from three to eight months after the conclusion of therapy revealed that all of them had maintained their improvement. Brady believed that severe frigidity, characterized by extreme feelings of anxiety, disgust, or anger, sometimes accompanied by physical pain, is quite refractory to treatment by either direct counseling techniques or intensive psychotherapy.

Haslam (6) described two cases of severe psychogenic dyspareunia in which a variant of systematic desensitization was used with rapid and entirely successful results. Size-graduated glass bougies were inserted in the patient's vagina and maintained in position by the therapist at first and then by the patient. During this procedure, the therapist reassured the patient and encouraged her to relax. In both cases, intercourse soon became "normal, satisfactory, and pleasurable." These terms were not specifically defined, nor did Haslam report the number of failures (if any) with this approach. He stated that relapse was most improbable in that the "anxiety-relieving properties of sexual responses could be predicted to support and continue to prevent any recurrence once intercourse was being enjoyed." It goes almost without saying that the particular nature of this technique would give pause to the vast majority of psychiatrists in this country, even those willing to try behavioral methods.

Kraft and Al-Issa (7), Ince (8), and Dengrove (9) each reported a single case of frigidity successfully treated with relaxation and desensitization.

BEHAVIORAL TREATMENT OF DYSFUNCTION IN MEN

The largest series of cases of impotence treated by behavioral techniques was reported by Wolpe (2), who used desensitization, sexual responses, and assertive responses (singly and in various combinations) in the treatment of eight cases of impotence. Five of the eight were considered "apparently cured" and three were "much improved" at the conclusion of therapy. The mean length of therapy was 9.8 months, with a mean of 30.6 interviews. However, Wolpe gave no consistent criteria for cure or improvement. He provided follow-up data for three of the cases, ranging from six months to two years and eight months after therapy ended. In each instance the patient maintained his improvement.

Dengrove (9) briefly described three cases of impotence successfully treated with systematic desensitization. He did not indicate specific criteria for recovery, nor did he mention any therapeutic failures. Ince (8) and Lazarus and Rachman (10) each described a single case of impotence successfully treated with systematic desensitization.

Case Report

The following is a brief illustrative history of a case of impotence I treated with relaxation and systematic desensitization.

The patient, a 36-year-old lawyer, was truly unusual in that he had never masturbated—he had never tried to nor wanted to. In fact, he had never experienced orgasm and ejaculation while in the conscious waking state (including periods of sexual activity with his wife), although he had occasional nocturnal emis-

sions. He had been married for six years to a sexual naïf who enjoyed sex and was unaware of his ejaculatory flaw. He had never discussed this with her. He found all aspects of sexual relations "repulsive, disgusting, and dirty." He was "afraid" of ejaculation and "dreaded" intercourse. He obtained erection with considerable difficulty and often not at all. During his infrequent coitus, he always lost his erection within three minutes. He had been in analytic psychotherapy for two years, twice weekly, with a worsening of his symptoms.

Sixty-eight relaxation/desensitization sessions over a two-year period produced exceptionally good results, but unfortunately the patient did not achieve orgasm. He was eventually able to engage in all the forms of sexual expression that had originally evoked his revulsion, including nocturnal emissions, manual stimulation of his wife's vagina, cunnilingus, and intercourse. His affect was rather neutral at first, but he later felt a positive sense of enjoyment of these activities. He became capable of continuing intercourse for as long as 10 minutes and experienced greater physical sensation in his penis than he had before.

This is as far as conditioning therapy has been able to take the patient to date. It may be that he will never experience orgasm in the conscious, waking state, but the improvement in his overall sexual performance has been nothing short of remarkable.

I have treated three other impotent patients with relaxation/desensitization, combined with hypnosis in two cases. My indices of improvement were the ability to obtain and maintain erection, the duration of intercourse, the frequency of successful intercourse, and the patient's degree of enjoyment. At the conclusion of therapy, one of these patients was apparently cured, one was moderately improved, and one was slightly improved.

CONCLUSIONS

The literature seems to indicate that behavior therapy has considerable merits in the treatment of sexual disorders. My results in treating impotence tend to confirm this conclusion. The behaviorists who write on the subject are in almost universal accord that behavior therapy (encompassing desensitization, sexual responses, and assertive responses) is the treatment of choice in frigidity and impotence and that the usual psychoanalytic and psychotherapeutic techniques are vastly inferior by comparison. Whether those skilled in the analytic method would agree with this position is a point for consideration. Obviously, the behaviorist is likely to treat only the therapeutic failures of the analytic school rather than its successes.

Among the behaviorists whose work I reviewed for this study, only Rachman (11) urged a degree of caution. He stated that the results of behavior therapy in sexual disorders "have been promising .... Perhaps the best attitude at this time is one of cautious optimism."

It is unfortunate that six of the nine clinical papers I have reviewed (4, 6, 7–10) revealed only their successful outcomes without indicating whether there were patients who did not fare well with behavior therapy. However, the three studies that took into account possible therapeutic failures as well as successes (2, 3, 5) reported high improvement rates (56 to 100 percent).

Despite the rather affirmative statements of some authors (3, 6, 8) about the permanence of results, I think that Dengrove (9) has some very wise things to say. He stated that the behavioral approach "presupposes a sexual partner who is willing to go along with the treatment as outlined, who is patient and understanding .... Without an understanding and cooperative spouse it hardly seems worthwhile attacking the problem at all" (pp. 52, 54). One of my cases affirmed this observation. Understandably, many instances of sexual disorders are closely allied to severe marital discord. It would be only logical to assume that desensitization therapy for patients in discordant marriages would result either in direct failure or quick relapse, thus lowering general improvement rates.

Despite the reservations I have mentioned, I am led to conclude on the basis of my review of the literature and my own clinical experience that desensitization therapy is of definite value in the treatment of frigidity and impotence. I feel that psychiatrists would do well, for themselves and their patients, to master this method.

Short-Term Treatment of Sexual Problems: Interim Report

BY JON K. MEYER, M.D., CHESTER W. SCHMIDT, JR., M.D., MARY JANE LUCAS, R.N., AND ELAINE SMITH, R.N.

Of 52 couples requesting treatment for sexual disorders, 16 were treated in accordance with the protocol of Masters and Johnson except that most were seen once a week for 10 or more weeks rather than daily for a briefer period. The treatment results were less successful than those obtained by Masters and Johnson. The authors believe that the successes of this approach nonetheless suggest a need to reevaluate the degree to which sexual problems may be conditioned responses. They also stress the need for specifying the degree of improvement among nonfailures for purposes of comparison and follow-up.

THE EXISTENCE OF PROGRAMS for the evaluation and treatment of sexual disorders is largely due to the courage and innovativeness of Masters and Johnson and to the professional and public impact of their work.

Their earlier work on the anatomy and physiology of human sexual response (1) led to the reexamination of such long-standing concepts as vaginal versus clitoral orgasm. Their later work (2) systematized and popularized short-term behavioral techniques for dealing with common sexual disorders. This has posed other questions for investigation, including the following: 1) the degree to which sexual disabilities occur independently of psychiatric conditions, 2) the etiologic contributions of neurosis or character disorder, and 3) the efficacy of short-term techniques that make no attempt to resolve internal conflict. In addition, we must weigh very practical issues related to cost-effectiveness. The possibility of rapid, permanent reversal of sexual problems in close to 80 percent of patients has great appeal.

Thus, there are both practical and theoretical issues in any examination of the psychological characteristics of sexually troubled patients and the outcome of directive, short-term treatment techniques. Masters and Johnson have pointed to the need for other workers to confirm their results (2). This obvious need, and the absence of other series, prompted the preparation of an interim report of our ongoing work at the Sexual Behaviors Consultation Clinic of Johns Hopkins University.

Revised version of a paper read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

The authors are with the Department of Psychiatry and the Sexual Behaviors Consultation Unit of the Johns Hopkins University School of Medicine, Baltimore, Md. 21205, where Dr. Meyer is Assistant Professor of Psychiatry and Surgery, Dr. Schmidt is Associate Professor of Psychiatry, and Mses. Lucas and Smith are Instructors in Psychiatry. Dr. Meyer is also Director of the Sexual Behaviors Consultation Unit, Dr. Schmidt is Associate Director, Ms. Lucas is Assistant Director, and Ms. Smith is senior staff member.

METHOD

We analyzed diagnoses (sexual and psychiatric, with psychiatric symptoms or traits as a separate category) and other significant factors of patients we saw between November 1971 and December 1973. These couples (most of whom were self-referrals) sought consultation for a self-designated "primary" sexual problem rather than more generalized psychiatric symptomatology. Some couples expressed a preference for treatment "like Masters and Johnson."

Characteristics of the Consultees

The 52 couples we screened showed a bimodal distribution in the Hollingshead (3) classes as follows: class I, 33 percent; class II, 36 percent; class III, 6 percent; class IV, 23 percent; and none in class V (2 percent of the subjects were unclassifiable). This distribution was probably related to the clinic's dual-fee structure.

Diagnoses were assigned very carefully. Sexual diagnoses were limited to those conditions usually considered responsive to direct short-term treatment—impotence, premature ejaculation, ejaculatory incompetence, dyspareunia, anorgasmia, vaginismus, and nonspecific sexual withdrawal. Paraphilias were considered psychiatric diagnoses. Two levels of manifest psychiatric problems were distinguished: symptoms and/or character traits, and full-blown neurosis, character disorder, or psychosis. A diagnosis of neurosis, character disorder, or psychosis was not assigned unless there was clear indication of syndromes that met the criteria of the *Diagnostic and Statistical Manual of Mental Disorders* (4). However, isolated symptoms or morbid personality traits were noted, even when we considered them insufficient to establish a diagnosis.

Considerable effort was made to avoid the logical inconsistency of using sexual and related symptoms to diagnose both a sexual disorder and a neurosis. For example, a patient with obsessive concern about impotence was listed only as impotent unless there was clear evidence of obsessive thought in other spheres such as nonsexual social interaction. When patients had both diagnoses and symptoms or traits, diagnoses were considered

preemptive. However, symptoms not contributory to the diagnoses were categorized separately.

Premature ejaculation and impotence were the most frequent diagnoses among the male consultees, with 21 percent and 19 percent, respectively, of the men falling in these categories. Obsessive-compulsive personality, diagnosed in 17 percent of the consultees, was by far the most frequent psychiatric diagnosis. Of the 52 women, 52 percent were diagnosed as having anorgasmia of varying degrees (orgasmic failure with coitus only or failure with both coitus and masturbation). Depressive neurosis and hysterical neurosis were common psychiatric diagnoses, occurring in 15 and 31 percent of the consultees, respectively. There was no observable socioeconomic trend in either single diagnoses or diagnostic combinations.

This group of lower-middle to upper-middle class individuals seeking consultation for sexual disorders showed a wide variety of sexual and psychiatric diagnoses and psychiatric symptoms or traits. There were several observations that were significant (see table 1). A sexual diagnosis alone was made in only 7.7 percent of the men and 19 percent of the women. In 27 percent of both men and women, both sexual and psychiatric diagnoses were made. In 25 percent of the men and 19 percent of the women, the psychiatric diagnosis was the only diagnosis, and in 67 percent of the men and 62 percent of the women, psychiatric diagnoses or symptoms or traits contributed to the problems for which help was sought.

TABLE 1
Diagnostic Classification for 52 Consultee Couples

Classification	Men		Women	
	Number	Percent	Number	Percent
Sexual and psychiatric diagnoses	14	26.9	14	26.9
Sexual diagnosis and psychiatric symptoms and/or traits	4	7.7	6	11.6
Sexual diagnosis only	4	7.7	10	19.2
Psychiatric diagnosis only	13	25.0	10	19.2
Psychiatric symptoms and/or traits only	4	7.7	2	3.9
No diagnoses and no symptoms and/or traits	13	25.0	10	19.2

Characteristics of the Treatment Group

Several factors excluded some of the 52 couples from short-term treatment, e.g., unwillingness to commit time or financial resources, anxiety about treatment, or the presence of neurotic disorders with severe classical symptomatology that we judged to be more appropriate for psychotherapy or psychoanalysis. The 16 couples we treated were highly selected, as was the group treated by Masters and Johnson (2).

The average age of the 16 men in the treatment group was 35, with a range of 23 to 52. The women's ages ranged from 23 to 53, with an average age of 33. All of the treated individuals were Caucasian. The couples had been married an average of 10 years, with a range of 1.5 to 29 years. The majority were in Hollingshead (3) classes I and II (31 and 50 percent, respectively); 6 percent were in class III and 13 percent in class IV. The chief female complaints related to lack of sexual satisfaction—often lack of orgasm in coitus. Male complaints were of performance inadequacies, usually impotence or inadequate ejaculatory control. In 3 of the 16 couples, the complaints included threats of separation.

Forty-four percent of the men had sexual diagnoses, as did 87 percent of the women (for the entire group of consultees, these figures were 42 percent and 58 percent, respectively). In terms of psychiatric diagnoses or symptoms or traits, this trend was reversed: 75 percent of the men versus 63 percent of the women. For the consultees, these percentages were 67 and 62, respectively. The group treated showed somewhat higher levels of pathology than did the larger group of consultees.

TREATMENT RESULTS

The 16 couples were seen by two dual-sex teams of therapists (J.K.M. and M.J.L., C.W.S. and E.C.). We followed the protocol of Masters and Johnson (2) except that 13 of the 16 couples were seen weekly rather than daily, for a total of 10 or more sessions. A factor in the choice of a weekly program was our experience with a 10-week symptom-focused treatment for psychosomatic problems (5). The weekly format is now an accepted technical variation in most centers. When treatment ended, we were available by telephone or for consultation at any time. We attempted a personal posttreatment follow-up at 6 weeks, 6 months, 1 year, 18 months, etc. for all cases (average follow-up was 7 months). Patients were reevaluated by their treatment team at follow-up.

Table 2 summarizes the data by couple for psychiatric and sexual pathology and initial and follow-up results. "Marked improvement" indicates apparent complete relief of the targeted sexual problems, "improvement" denotes substantial gains but not complete relief, "equivocal improvement" indicates some minimal positive change in the sexual symptoms, and "no improvement" means there was deterioration or no change.

Outcome: The Couple as the Unit

Judgments of treatment efficacy were first based on the couple as a unit, an approach rationalized by the treatment method, which presupposes shared problems and views the couple as the "patient." From this perspective, 4 of the 16 couples (25 percent) showed marked initial improvement. For couples, "marked improvement" indicates that the primary sexual dysfunction in both partners was relieved. There was improvement in 25 percent of the couples (N=4) and equivocal improvement in 31 percent (N=5). No improvement or deterioration was noted in 19 percent of the partnerships (N=3).

As is shown in table 2, 3 of the 4 couples with initial marked improvement showed similar levels of functioning at follow-up. (The fourth case was lost to follow-up.) Two of the 4 improved couples maintained their improvement at follow-up; there was decreased ejaculatory con-

TABLE 2
Diagnostic Classification and Initial and Follow-Up Results for 16 Treatment Couples

Couple Number	Sexual Diagnosis		Psychiatric Diagnosis		Psychiatric Symptoms and/or Traits		Results*	
	Man	Woman	Man	Woman	Man	Woman	Initial	Follow-up
1	no	yes	yes	no	no	yes	MI	MI
2	yes	no	yes	no	no	no	MI	MI
3	no	yes	yes	no	no	no	MI	MI
4	yes	no	yes	no	no	no	MI	U
5	yes	yes	no	yes	no	no	I	I
6	yes	yes	no	yes	no	no	I	I
7	yes	yes	yes	no	no	no	I	EI
8	no	yes	no	yes	no	no	I	EI
9	no	yes	yes	no	yes	no	EI	EI
10	yes	yes	yes	no	yes	no	EI	EI
11	no	yes	yes	yes	yes	yes	EI	NI
12	yes	yes	yes	yes	no	no	EI	NI
13	no	yes	yes	yes	yes	no	EI	NI
14	no	yes	no	yes	yes	no	NI	NI
15	no	yes	yes	yes	no	no	NI	NI
16	no	yes	yes	yes	no	no	NI	NI

*MI = marked improvement, I = improvement, EI = equivocal improvement, NI = no improvement or deterioration, U = unknown (lost to follow-up).

trol in the third and return of dyspareunia in the fourth. Among the 5 couples who showed equivocal improvement, 2 maintained the general gains and 3 deteriorated to pretreatment levels. None of the 3 couples initially deemed failures improved over time.

Outcome: The Individual as the Unit

Seven men and 14 women in the treatment group manifested sexual disabilities. Five of these men showed initial marked improvement and 2 showed equivocal improvement. At follow-up, 3 of the 5 markedly improved men maintained high levels, 1 dropped to the improved category, and 1 could not be reached. Of the 2 men with equivocal improvement, 1 maintained that level and the other dropped to a pretreatment level of functioning. Of the 14 women with sexual disability, 8 showed no initial improvement, constituting the major reservoir of failure. Two showed initial marked improvement, 1 showed improvement, and 3 were rated equivocal. At follow-up, the 2 women with marked improvement maintained that level. One individual from each of the next two categories (improved and equivocally improved) dropped by a level at follow-up. Individuals without a specific sexual disability at the start of treatment remained disability-free during treatment and follow-up.

DISCUSSION

Psychiatric Problems Associated with Sexual Difficulties

In this series of patients, we found a high incidence of associated psychiatric difficulty in patients requesting treatment for common sexual problems. These results, however, are not strictly comparable to others in the literature. For example, Maurice and Guze (6), using different criteria with patients in their second week of treatment at the Reproductive Biology Research Foundation in St. Louis, Mo., reported that one fourth of the men and one-third of the women in the sample qualified for psychiatric diagnoses. At the other end of the spectrum, O'Connor and Stern (7) reviewed 96 psychoanalytic clinic patients with sexual dysfunction and found that all of them had both psychiatric and sexual diagnoses.

Our facility at Johns Hopkins falls somewhere between O'Connor and Stern's psychoanalytic clinic and the Reproductive Biology Research Foundation in its approach. Since diagnosis involves discrimination, even in the choice of criteria, treatment results reflect the bias of the diagnostician. In addition, however, it seems likely that patient self-selection is operating in line with the known orientation and services of a particular treatment facility. Patients appearing at a psychoanalytic clinic may do so out of a sense that analysis will best fit their needs. Patients appearing at the Foundation in St. Louis may have the opposite feeling.

Patient Selection for Short-Term Directive Work

Masters and Johnson (2) indicated that exclusions from treatment were based on the presence of psychosis, the "psychoneurotic" being acceptable. In 1973, they seemed to indicate some increased concern about the prevalence of neuroses and their potential for complicating treatment (8). Kaplan and Kohl (9) outlined some adverse reactions, emphasizing careful assessment not only of the sexual disability but also of the psychiatric status. They suggested exclusion of patients "in a depressed or highly conflictual state . . . not primarily reactive to the sexual problem . . ." and noted "relatively rare" instances in which the sexual symptom constitutes a major defense.

In our experience, sexual disability was often noted during evaluation and treatment in a context of neurosis

and/or character disorder. Often the issue had less to do with the absence of such problems than the degree to which they might be ignored in short-term, focused treatment. For example, a patient we saw with anorgasmia, obsessive fear of loss of bowel control, and agoraphobia was felt to be better suited for psychotherapy. On the other hand, a minimal character disorder or a neurotic symptom that was mildly inconvenient at the outset of treatment often became more marked during treatment, but not necessarily in a way that interfered with the Masters and Johnson protocol. In most cases, the sexual symptom was acceptable at some level as a compromise between more adequate function and the hazard of greater anxiety or failure. The issue was how overdetermined such patterns might be.

Treatment Experience

Our experience indicates that short-term behavioral treatment of sexual disorders may be wholly or partially successful in a number of instances and that substantial success tends to be maintained at follow-up. In other cases, focused treatment works less well and the minimal gains seem subject to deterioration. In this series, it was easier to achieve and maintain control with male performance problems than with female difficulties (see table 2). There was a tendency for higher degrees of nonsexual psychopathology (i.e., cases 1–8 versus cases 9–16 in table 2) to be associated with less initial improvement and poorer maintenance of that improvement at follow-up.

Over the course of treatment, appreciable links became manifest among the sexual problems, other symptomatic material, and nonsexual behavior patterns. The symptoms and/or traits, seemingly of minor significance during evaluation, often contributed materially to difficulty during treatment. In some instances, neurotic and character formations related to the sexual disability seemingly emerged de novo during treatment. Transference distortions of the therapeutic relationship and goals were virtually universal, serving to make the presenting sexual disability more comprehensible. It must be emphasized that we proceeded in a directive, educative, goal-oriented fashion in treatment and did not seek to elicit transference, genetic, or conflictual material—such material intruded itself into the ongoing work. Follow-up to date suggests that improvement in some cases may be thought of in the framework of a transference cure, related to overwhelming superego restrictions and at least partially dependent on the presence of the therapists.

Categorization of Treatment Results

Masters and Johnson (2) reported their treatment results in terms of failure rates, with an overall initial failure rate for marital units of 18.1 percent. Initial failure rate "is defined as indication that the two-week, rapid-treatment phase has failed to *initiate* reversal of the basic symptomatology of sexual dysfunction . . ." (emphasis added). Our initial failure rate for marital units was 19 percent, which is almost equivalent to Masters and Johnson's. The failure rate alone, however, did not describe the varying degrees of improvement within nonfailure units.

It seems necessary for purposes of follow-up and later comparison to specify the degree of improvement among nonfailures. While no follow-up figures are available from Masters and Johnson for marital units, our 7-month follow-up failure rate was 37 percent, the new failures being couples who showed only equivocal initial improvement.

Our success rates for dysfunctional individuals, where the improvement of one partner did not blur the failure of the other, were less positive overall than those reported by Masters and Johnson (2) and were similar to those from other psychotherapeutic modalities (10). It should be noted that the success of Masters and Johnson with primary impotence, secondary impotence, "random orgasmic inadequacy" (in women), and aging men and women was less impressive than their overall treatment results. Contributing to their better overall results were higher success rates in such categories as premature ejaculation, ejaculatory incompetence, primary orgasmic dysfunction, and coital orgasmic inadequacy (2, pp. 351–369). Secondary impotence and random orgasmic inadequacy were highly represented in our series and may account for our less positive results.

CONCLUSIONS

Our current task is to review a treatment modality that is gaining increasing acceptance in medicine and psychiatry, exploring its limitations and strengths, its indications and contraindications, and integrating it within the general body of psychiatric experience. It has seemed important to do our patients a service in terms of increased cost-effectiveness without unproductively simplifying complex intra- and interpersonal issues.

In the majority of our cases, sexual disorders were accompanied by symptoms of psychiatric disturbance. Treatment and follow-up experience indicated that the sexual disability often could not be disentangled from intrapsychic dynamics which limited the degree of mechanical rehabilitation and the capacity for subjective intimacy. Experience in conventional treatment of neurotic problems, however, is often the obverse, i.e., most ramifications of the neurosis may yield, while the sexual dysfunction tenaciously repeats itself.

Certain aspects of sexual problems were usually more or less allied with neurotic or character problems, but with varying amounts of freedom in the alliance. The strength of this alliance was a crucial factor in short-term outcome. Other aspects of sexual problems seemed conflict-free, representing misinformation, habit, poor technique, and more superficial problems in relationships. The fact that the Masters and Johnson techniques were strikingly successful in certain instances indicates the necessity for a reevaluation of the degree to which sexual problems may be culturally determined or become secondarily autonomous (i.e., persisting although they no longer serve a defensive function). Sandler and Joffe (11)

refer, for example, to psychological structures originating out of conflict but persisting even though the original impulses are no longer operative in the same way. They suggest that problematic structures of this type are amenable to behavior therapy.

It is important to recognize that a variety of modalities are useful in the treatment of sexual problems, depending on the individual and the disability. Rather than an a priori set toward one particular treatment mode, dynamic or behavioral, the specific technique should be judiciously selected according to individual capacities, symptomatology, character traits, lifestyles, motivation, and therapeutic goals.

On the basis of accumulated clinical experience, perhaps the most one can say at this time is that any sexual disability has two components—a neurotic component related to internalized conflict and a habitual conditioned response mode related to repeated partial gratifications. It may turn out that the treatment of choice in the rehabilitation of sexual disability will be a tandem approach to both aspects of the problem. As Kestenberg (12) observed, most patients suffering from a sexual disability cannot be completely educated in sexual functioning until relief of conflict has rendered them educable. But standard psychotherapies do not offer direct education; this is the province of directive techniques.

DISCUSSION

JOHN F. O'CONNOR, M.D. (New York, N.Y.)—Dr. Meyer and associates present an informative review of the treatment of sexual disorders at Johns Hopkins using the Masters and Johnson protocol, modified by extending the time frame. Their study of the total group of consultees presents some interesting findings, and their methodology is excellent.

Sexual therapy is quite new to American psychiatry, although there are reports of the results of hypnosis dating back to the late 19th century and of behavioral therapy from the late 1940s. The vast majority of work in this field, however, postdates Masters and Johnson's pioneer effort. Five years ago, their treatment was considered a fad by many, but a more serious approach is now being taken. It is most encouraging that many of those who are using the Masters and Johnson technique are validating and publishing their results. This introspection and willingness to deal with failures have added credibility to the field.

In the psychiatric literature of the past 50 years, sexual disorders were virtually always related diagnostically to severe neurosis and psychosis. Dr. Meyer and associates examined this relationship and found that there are in fact patients who suffer sexual disorders but do not have a definitive psychiatric diagnosis. In our rapid-treatment population at the International Institute for the Study of Human Reproduction at Columbia University, we have an even higher proportion of patients for whom a psychiatric diagnosis cannot be definitively established. Many of these patients are all too "normal." One gets the impression such patients have given up libidinal expression and drive in order to maintain societal (parental) approval. The dysfunction is not seen as an autonomous ego function, but rather as extreme suppression and denial manifested in the psychophysiological sphere that enables the individual to avoid what seems to him to be a catastrophic anxiety. One finds evidence of dysfunction in other areas in these individuals (e.g., career and interpersonal relationships), although this is much more subtly manifested.

In our experience, the Masters and Johnson therapy protocol is by far the most effective to date. It offers many advantages, the most important of which is that it allows both partners to understand in detail which of their interactions are leading to symptom development or maintenance. However, only the middle and upper socioeconomic groups can be treated by this method as it was originally designed because of the large investment of time and money it requires. Dr. Meyer and his coworkers have offered an alternative—Masters and Johnson-type treatment on a weekly rather than daily basis in a clinic with a dual-fee structure.

We look forward to further detailed reports from these authors and others involved in sexual therapy.

Difficulties in Brief Conjoint Treatment of Sexual Dysfunction

BY MELVIN R. LANSKY, M.D., AND CAPT. ADELAIDE E. DAVENPORT, USAF

The authors offered conjoint treatment of sexual dysfunction to an unselected population in a military hospital for one year. Of the 10 couples who requested treatment, 7 were treated by techniques outlined by Masters and Johnson. The couples who completed the treatment exercises improved, and neurotic interactions, presumably resulting from the symptoms, often disappeared. The couples who avoided the exercises had interactional patterns dominated by projection and blame, sadomasochism, and depressive features; typically their marital difficulties were aggravated by the treatment.

THE WORK OF MASTERS AND JOHNSON has made monumental contributions to our knowledge of human sexual dysfunction. These authors and their coworkers have added knowledge about human sexual response (1), developed a treatment program aimed at short-term symptomatic treatment (2, pp. 1–91), and studied the results of treatment in one of the most rigorous evaluation programs ever done (2, pp. 351–369).

With a selected patient sample, their results are impressive. Compared in terms of failure rates after short-term treatment, the overall failure rate for male disorders of all kinds is 16.9 percent and that for female disorders is 19.3 percent. Failure rates after a five-year follow-up are only slightly higher, demonstrating a low reversal rate for therapeutic success and an overall failure rate for all disorders in both sexes of about 20 percent.

But such results apply largely to highly motivated patients who are of relatively high social, educational, and financial status and are relatively free from psychopathology other than symptoms of sexual dysfunction. Almost 90 percent of their sample of 790 patients did not live in St. Louis (the location of the treatment program) and were sufficiently motivated and financially able to make the trip. Seventy-two percent were college graduates, 17.5 percent were physicians, and half of the physicians were psychiatrists.

At the time this work was done the authors were with the Department of Mental Health, Wilford Hall USAF Hospital, Lackland Air Force Base, Tex., where Dr. Lansky was Staff Psychiatrist and Capt. Davenport is a social worker. Dr. Lansky is currently Assistant Professor in Residence, University of California, Los Angeles, Medical School, and Staff Psychiatrist, Brentwood Veterans Administration Hospital, Los Angeles, Calif. Address reprint requests to Dr. Lansky, 3940 Sapphire Dr., Encino, Calif. 91436.

The opinions expressed here are those of the authors and do not necessarily reflect the views of the Department of the Air Force.

No patients other than physicians were accepted unless they were referred from a treatment authority. Most patients had symptoms of sexual dysfunction only. Psychoneurotic patients were accepted; psychotics were not. Both partners had to be interested in reversing the disorder. The couple had to be adjusted to their social community, understand the procedures involved, and, in most cases, had to pay the fee.

One chapter of *Human Sexual Inadequacy* (2, pp. 370–391) is devoted to treatment failures, but, by and large, this is the least satisfactory part of the study. Masters and Johnson demonstrated the effectiveness of their techniques for motivated patients free of psychopathology other than their presenting symptoms, but their discussion of what went wrong in unsuccessful cases is of little help in ascertaining when and for whom such techniques may be of help in an unselected, local population.

Regrettably, literature adding to our knowledge of what goes wrong in treatment failures is hard to come by. Dynamically oriented studies (3, 4) usually point to the dynamics presumed to underlie the sexual difficulty, rather than to the difficulties in treatment itself; more behavioral studies tend to use case material as illustrative of what is being done (5) or to give overall results (6), again without examining treatment difficulties. Studies antedating the work of Masters and Johnson usually do not consider treating the couple as a unit and consequently are of little value in highlighting difficulties in such treatment.

METHOD

This paper reviews a one-year treatment program conducted by a team of cotherapists in a military general hospital in San Antonio, Tex. Patients were active-duty and retired military personnel and their families. A total of 10 couples presented themselves for treatment; 8 were offered treatment for symptomatic sexual difficulties, and 2 were treated conjointly in psychotherapy sessions for marital disharmony. The sample differed from that of Masters and Johnson in several important ways. Treatment was local and without cost, and any couple requesting treatment was treated. Patients tended to be of lower social, economic, and educational status—8 of the 10 men were enlisted men.

Treatment consisted of three to four hourly sessions a week for two to four weeks. At a preliminary session, couples were told not to embark on treatment unless they could attend all sessions and devote a large amount of time each evening to prescribed exercises. Difficulties

that could be anticipated were discussed in advance. These included job demands, children, other obligations, and anxieties about the treatment itself. Each spouse was seen once individually by each cotherapist; thereafter, cotherapists met only with the couple as a unit.

The treatment technique, similar to that outlined by Masters and Johnson, stressed anxiety reduction, instruction by cotherapists, and communicative openness. The couples started by alternately giving and receiving pleasure, the "pleasured" partner asking for what he or she wanted, other than genital or breast stimulation or intercourse, which were forbidden. Intercourse at times other than the exercises was discouraged. Other activities were added when pleasuring experiences were consolidated, when communication had started, and when anxiety was reduced (this often occurred very quickly). These included manual genital stimulation (7) and the squeeze technique (2, pp. 92–115), where appropriate. In cases of premature ejaculation, the couple practiced vaginal containment without movement before they had intercourse. As couples proceeded to intercourse, instruction on various positions was given. Throughout the treatment the cotherapists tried to keep the marital partners out of a performing role and to facilitate each partner's asking for what was wanted and discussing what was disliked. A synopsis of treatment results is given in appendix 1.

DIFFICULTIES

It is striking that virtually no scheduled therapy session was missed by any of the 7 couples. (One couple, designated in appendix 1 as couple H, dropped out when the wife refused treatment.) In the treatment hours themselves there were very few difficulties posed by anxieties over specifically sexual matters: e.g., performance, the exercises, or talking about sexual matters. Active didactic and supportive interventions by the cotherapists were largely successful in reducing anxiety and facilitating communicative breakthroughs. Domination of the hours by conflictual issues aside from sexual matters or the refusal of one or both partners to discuss any matter was ominous for the prognosis.

By far the most striking difficulty was in doing the nightly exercises. A task was assigned each night that was clearly defined in terms of what was to be done and how much time was to be spent. Of the 7 couples in treatment, only couple B did the exercises unfailingly. Those who did the exercises consistently improved symptomatically; no symptoms improved in couples who did not do them. In the latter group, even vigorous interpretation by the therapists and warnings that the couple was avoiding treatment did not reverse the failure to do the exercises.

The cotherapists terminated treatment for couples D and E because several weeks of treatment failed to stop sadomasochistic and depressive trends during treatment hours and because the couple persistently failed to do the exercises. Couple F dropped out of treatment when couples psychotherapy was suggested for the same reasons. Couple G decided to divorce, and Mrs. H refused treatment. Couples I and J decided on couples psychotherapy at the outset. Treatment of couple C was terminated when Mrs. C became suicidal and was hospitalized.

A word must be said about the cotherapists' handling of difficulties in the treatment. Since the couples had agreed in advance to make time for therapy sessions and nightly exercises, the cotherapists felt free to inquire about anxiety when exercises were missed or there was difficulty discussing sexual experiences in therapy sessions. Very often an explicit source of anxiety was evident or surfaced easily, but reasons other than anxiety were frequently given for not pursuing the agreed-upon task.

It was not uncommon for couples with sexual dysfunction to have schedules that left them with little time together—children interfering, colds, feeling tired, guests, sudden business, overextended social obligations, and many other excuses were encountered. In each case, the question of avoiding treatment was raised. This focus on opposition to the treatment process, presumably due to anxieties beyond the couples' awareness, has much in common with the focus on resistance in psychoanalysis. Sandler and associates (8) argued that the concept of resistance may be extended to clinical situations other than psychoanalysis.

DISCUSSION

The differences in results of the sample described here and that of Masters and Johnson are striking. Of the 10 couples in our sample, only 2 (couples A and B) left with totally satisfactory results. Even though the sample size does not permit tests of statistical significance, some discussion of the differences is necessary.

1. Treatment was largely based on the technique outlined in *Human Sexual Inadequacy* (2), but the frequency of missed exercises necessitated more emphasis on avoidance of treatment.

2. The effect of the particular therapists on outcome is always open to question, but the therapists had notable success with those couples who did the exercises. In fact, it was striking that all the couples who did the exercises improved symptomatically (even Mrs. C, who became suicidal).

We were most struck with differences between those couples who improved (couples A, B, and C) and those who did not (couples D through H).

The improved group had come for therapy shortly after their difficulties became apparent. Couple A presented after the husband's severe cervical spine injury. Couples B and C came several months after the birth of a child they anticipated would be their last. Interactional patterns that could be called neurotic were observed in these couples, but they were largely referable to difficulties resulting from the symptom. These patterns included inhibition, frustration, overt anxiety, fear of performing, and fear of failure. They were strikingly accessible to discussion, and the neurotic patterns could be seen to be a result of the symptom rather than its cause (9). In striking contrast to the unimproved group,

these couples did the prescribed exercises, albeit with anxiety at times, and all improved symptomatically.

The unimproved group had symptoms that had existed for a long time. Interactions often involved projection, blame, contempt for the spouse, sadomasochistic and depressive features, and a sense of fearing intimacy that the treatment probably aggravated. In each case an "agenda" between the couple became evident; this agenda extended far beyond the symptom or its consequences and the symptom tended to reinforce or justify it. Couple D became involved in a sadomasochistic scenario involving the wife's failure to clean the house. Mrs. E openly rejoiced in her husband's inadequate performance. Mrs. F persistently complained of being used for sexual purposes only. Couple G talked of different financial aspirations and of divorce. Mrs. H appeared only once in order to prove that the sexual difficulties were her husband's fault. Strikingly, none of the couples ever did the exercises, with the dubious exception of couple G, who talked of divorce during their one try. It is quite likely that the prescribed intimacy brought into focus issues that the marriage was organized around avoiding and that the prospect of symptom removal highlighted more general dissatisfaction with the marriage.

These results from an unscreened sample point to the need for therapists to employ powerful techniques for symptom removal in situations and at times when they can be tolerated. The sample we treated is not large enough to warrant definitive generalizations, but it is hoped that future studies will highlight interactional features of prognostic significance that will help to integrate newer techniques into patients' overall treatment.

APPENDIX 1

Synopsis of Results of Conjoint Treatment of 10 Couples

Couple A: Both mid-20s. Husband referred for impotence presumably due to a cervical spine injury. Eleven sessions. Missed exercises twice. Totally satisfactory results.

Couple B: Both mid-20s. Premature ejaculation. Eleven sessions. Never missed exercises. Totally satisfactory results.

Couple C: Husband mid-40s with premature ejaculation. Wife mid-30s. Much improvement, but wife became suicidal and treatment was discontinued.

Couple D: Both late 30s. Husband referred for loss of erection in intercourse. Four sessions. Never did exercises. Relationship worse. Symptoms unchanged.

Couple E: Both early 40s. Selective impotence. Seven sessions. Never did exercises. Relationship and symptom unchanged.

Couple F: Both mid-20s. Premature ejaculation (and wife's orgasmic difficulties not identified at outset of treatment). Seven sessions. Never did exercises. Relationship worse. Symptoms unchanged.

Couple G: Mid-20s. Inability to ejaculate (and wife's orgasmic difficulties not identified at outset of treatment). Six sessions. Did exercises once while talking of divorce. Symptoms unchanged. Relationship worse.

Couple H: Both in 40s. Occasional impotence. Wife refused treatment.

Couple I: Both late 20s. Wife had difficulty responding. Elected couples psychotherapy on advice from therapists. Relationship improved. Symptom unchanged.

Couple J: Both late 40s. Sexual problems overshadowed by chronic alcoholism and longstanding marital problems. Couples psychotherapy was offered. Relationship and symptoms unchanged.

Affective Disorder: Studies with Amine Precursors

BY DAVID L. DUNNER, M.D., AND RONALD R. FIEVE, M.D.

The authors assessed the clinical antidepressant effects of L-tryptophan given alone and in combination with L-dopa in 12 patients with a diagnosis of primary affective disorder. Preliminary results did not demonstrate an antidepressant response when L-dopa was combined with L-tryptophan. Also, the results did not support the catecholamine or biogenic amine hypotheses of affective disorder.

THE PURPOSE of this paper is to relate preliminary clinical results of the administration of amino acid biogenic amine precursors to depressed patients. The use of L-dihydroxyphenylalanine (L-dopa) and L-tryptophan as experimental antidepressant agents is based on the catecholamine hypothesis (and later the biogenic amine hypothesis) of affective disorder, which suggests the possibility that relative or functional deficiencies of central nervous system concentrations of dopamine (DA), norepinephrine (NE), or serotonin (5-HT) may be associated with depressive states (1, 2). The treatment of these depressive states might then be related to increased brain concentrations of these amines.

However, the administration of amines alone would not result in increased brain amine concentrations, since the amines do not cross the blood-brain barrier. Therefore, a treatment strategy has evolved (the "precursor load strategy") based on the ability of precursors of biogenic amines, such as L-dopa and L-tryptophan, to cross the blood-brain barrier (3). Thus in animals and apparently in man, increased amounts of DA in the central nervous system result from administration of L-dopa, and, similarly, concentrations of 5-HT and metabolites are increased during administration of L-tryptophan (4–7).

In previous clinical trials of L-tryptophan in depression, Coppen and associates (8, 9) reported antidepressant effects equivalent to those obtained with electroconvulsive therapy or imipramine. However, these results could not be confirmed by Carroll and associates (10) or Murphy and associates (11).

Several investigators have administered L-dopa to depressed patients, attempting to alter central nervous system catecholamine metabolism in these patients and alleviate their depressive symptoms. Goodwin and associates (12) reviewed these studies and reported on the effects of L-dopa in 16 depressed patients who were studied at the National Institute of Mental Health. They noted that with L-dopa treatment patients with "retarded" depressions had an antidepressant response, while hypomanic-like episodes occurred in depressed patients who had histories of mania (13).

The unipolar/bipolar classification of depression had already been reported (14, 15). This classification separated depressed patients according to their histories of mania or hypomania. Bipolar-1 patients are those depressed patients who have a history of hospitalization for mania; bipolar-2 patients have been hospitalized for depression and have symptoms of hypomania not leading to hospitalization; and unipolar patients have depression only (16). When the L-dopa results from NIMH were reanalyzed using the unipolar/bipolar classification, it was noted that during L-dopa treatment bipolar-1 patients tended to develop manic-like states and bipolar-

2 patients demonstrated an antidepressant effect, but unipolar patients had no response (17).

Studies in animals suggest that the pharmacological effects of L-dopa include release of 5-HT from its storage sites, resulting in a decrease in 5-HT turnover (18, 19). The rationale for the present study was that the administration of L-dopa and L-tryptophan together might augment the turnover of both DA and 5-HT in brain and result in an antidepressant response, particularly in unipolar patients, who typically do not respond to L-dopa alone.

METHOD

The study was conducted on the metabolic clinical research unit of the New York State Psychiatric Institute. All patients met the diagnostic criteria of Feighner and associates (20) for primary affective disorder and were further described as bipolar or unipolar (16). All patients were studied during the depressed phase, were in good medical health, and voluntarily agreed to participate in these research studies.

The general design was to have a drug-free period of at least 10 days, followed by a placebo period (3 to 7 days), substitution of L-tryptophan (8.4–9 g per day) for 10 to 18 days, addition of L-dopa with a 6- to 13-day period of 4.5- to 6-g daily dose, and a 5- to 7-day postdrug placebo period. The dose of L-tryptophan was held constant during L-dopa treatment.

All medication was given on a double-blind basis, i.e., neither the patient nor the nurse rating team was aware of the periods of active drug administration. Behavioral ratings were performed three times daily by a nursing team trained to use a global rating scale for mood and twice weekly using a structured interview for assessment of symptoms of mania and depression. Clinical antidepressant responses to drug administration were evaluated in the following manner: "nonresponse" indicated no improvement in depression ratings in the last few days of drug treatment; "response" indicated that the patient improved during active drug administration and then had a period of relapse with placebo resubstitution; "equivocal response" indicated that the patient improved with the active drug but failed to have a postdrug placebo rebound depression; "worse" indicated the patient became more depressed during active drug treatment and improved with placebo resubstitution.

Following the double-blind trial, patients were treated in a nonblind manner with either tricyclic antidepressants or monoamine oxidase inhibitors. Behavioral ratings continued during this period of drug administration.

Vital signs were monitored several times daily and routine clinical laboratory tests were repeated, usually weekly. Patients were carefully observed for the presence of neurological side effects. All patients were maintained on a diet low in biogenic amine precursors throughout the study.

To date, 13 patients have been studied. The first 6 patients received L-tryptophan only. One patient was then given a 4-day trial of L-dopa and L-tryptophan and another patient had a 4-day trial of low doses of L-dopa at the end of a 16-day L-tryptophan study. Five patients received the combination of L-dopa and L-tryptophan for 8 to 19 days after trials of L-tryptophan alone.

Medication was given in three divided doses. Daily doses of pyridoxine (150 mg) and ascorbic acid (900 mg) were also administered during the placebo and active drug periods.

RESULTS

Double-Blind Administration of L-Tryptophan Alone

Of the 6 patients who received only L-tryptophan, 4 failed to have an antidepressant response, 1 had an equivocal response in that she improved but failed to have a posttryptophan worsening of depression, and 1 patient had a good antidepressant response to L-tryptophan. The results of these 6 patients and of a 7th patient who also did not have a clinical antidepressant response during either L-tryptophan treatment or 4 days of treatment with L-dopa are presented in table 1. Of the L-tryptophan nonresponders, 4 patients subsequently had a clinical antidepressant response to a nonblind trial of a monoamine oxidase inhibitor. One bipolar-I patient improved significantly during treatment with L-tryptophan but continued to improve when L-tryptophan was discontinued. She was then treated with lithium and was discharged from the hospital. In evaluating her drug response, we consider her improvement most likely to be related to a spontaneous remission. No drug side effects occurred during the L-tryptophan trials.

Double-Blind Administration of L-Tryptophan with L-Dopa

Five patients had prolonged trials of the combination of L-tryptophan and L-dopa, and their clinical results are presented in table 2. None of these patients had an antidepressant response during treatment with L-tryptophan alone. One patient had an antidepressant response as L-dopa was gradually increased to a daily dose of 6 g, but she failed to have a depressive rebound with placebo resubstitution. She was subsequently treated successfully with protriptyline. A second patient improved slightly during treatment with L-dopa and showed a relapse of depressive symptoms when placebo was substituted. He was then successfully treated with protriptyline and lithium. Although this patient had a history of hospitalization for mania, he did not develop a manic-like state during his 14 days of combined treatment with L-dopa and L-tryptophan.

The other 3 patients failed to improve after L-dopa was added. One patient had a psychotic depression that became much worse during the period of combined treatment, and she attempted suicide. Subsequently she was successfully treated with electroconvulsive treatments.

Symptomatic postural hypotension at 5 g of L-dopa was noted in 1 patient. Otherwise, no side effects, neurological signs, or laboratory abnormalities were noted.

TABLE 1
Response to L-Tryptophan Alone

Patient			L-Tryptophan Administration			Poststudy Treatment	
Age	Sex	Diagnosis	Daily Dose (g)	Number of Days	Response	Drug	Antidepressant Response

DISCUSSION

The theoretical basis of this study was that a possible reason for the lack of antidepressant response to L-dopa in certain depressed patients (particularly unipolar patients) could be related to the concomitant decrease in central nervous system 5-HT turnover during L-dopa therapy. Since L-tryptophan enhances turnover of 5-HT in brain, during the combined use of these drugs both the turnover of 5-HT, DA, and possibly NE would be augmented. Bunney and associates (21) reported 7 patients who received separate trials of L-dopa and L-tryptophan. Whereas some antidepressant effect was noted with each drug, treatment with imipramine resulted in a more pronounced improvement.

Although this is a preliminary report, the data obtained thus far in 3 unipolar patients fail to support the notion that an antidepressant response to L-dopa can be obtained by pretreating patients with L-tryptophan. The equivocal response seen in 1 unipolar patient was not as striking as her subsequent response to protriptyline. A second unipolar patient appeared to become worse during L-dopa treatment, and the third unipolar patient who had no response to combined treatment had a good antidepressant response to imipramine during an earlier hospitalization.

A general lack of antidepressant response to L-tryptophan alone was observed in most of these patients. Although some of these trials were of short duration, Coppen and associates (9) demonstrated an antidepressant response to L-tryptophan within 10 days of treatment by administering L-tryptophan alone to 8 patients with a mean age of about 55 who were described as unipolar depressives. It is unclear if any of their patients had histories of hypomania. Furthermore, their patients responded as well to L-tryptophan as to imipramine. The patients reported in our study were younger, which may be a source of the difference in the clinical results of the two studies. However, antidepressant effects of L-tryptophan could not be demonstrated by Carroll and associates (10) or by Murphy and associates (11), although a more recent study by Murphy and associates (22) noted that L-

tryptophan has some antidepressant effect in bipolar-I patients but not in unipolar patients.

Van Praag and Korf (23) reported that 3 of 5 depressed patients had an antidepressant response with 5-hydroxytryptophan (5-HTP), a more immediate 5-HT precursor than L-tryptophan. However, only 1 of 7 depressed patients studied by Brodie and associates (24) had a therapeutic response to 5-HTP.

The use of the precursor-load strategy to effect higher concentrations of biogenic amines in the central nervous system is predicated on the ability of amino acid precursors to cross the blood-brain barrier and be converted to functional biogenic amines. In the interpretation of the preliminary clinical results from our study, pyridoxine, a cofactor in the decarboxylation of 5-HTP to 5-HT (25), interferes with L-dopa metabolism, apparently through the formation of a chemical complex between L-dopa and pyridoxal 5-phosphate (26, 27). Thus further studies of combined treatment with L-dopa and L-tryptophan will need to consider the possible interference of pyridoxine with the desired biological effect.

CONCLUSIONS

The catecholamine hypothesis of affective disorders has provided a useful theoretical framework for the investigation of biological factors in depression. If central nervous system catecholamine metabolism is reduced in some depressions, certain depressions should be alleviated by the administration of biogenic amine precursors. Similarly, the administration of drugs that decrease catecholamine metabolism should result in improvement of manic states. Negative results from the administration of biogenic amine precursors to depressed patients and equivocal or negative results in mania using α-methyltyrosine, an inhibitor of catecholamine synthesis (17, 27), or fusaric acid, an inhibitor of dopamine-β-hydroxylase (28), have led several investigators to question the role of the catecholamine hypothesis as a basis for continued research in affective illness (29, 30).

Elevated Blood Serotonin Concentrations in Unmedicated Chronic Schizophrenic Patients: A Preliminary Study

BY EVANGELOS GARELIS, M.D., J. CHRISTIAN GILLIN, M.D., RICHARD JED WYATT, M.D., AND NORTON NEFF, M.D.

The authors found higher serotonin concentrations in the blood of unmedicated chronic schizophrenic patients than in the blood of medicated schizophrenic patients or normal control subjects. This finding is consistent with the previous observation that the level of monoamine oxidase activity is low in the platelets of chronic schizophrenics.

THERE ARE SEVERAL lines of research investigating the postulated changes of serotonin in schizophrenia (1, 2). One of the approaches has been the direct measurement of the amine or its metabolites in the body fluids of patients (1, 3–6).

Extending this approach to the study of enzymes participating in the metabolism of serotonin and other monoamines, we recently found that platelet monoamine oxidase (MAO) activity is significantly reduced in chronic schizophrenic patients and that this reduction is probably genetically determined (7, 8). Since serotonin is a substrate for platelet MAO where it is taken up from the plasma and stored (9), we speculated that platelet serotonin concentration would be elevated in schizophrenic patients compared to control subjects. We are reporting herein the results of a preliminary investigation on the levels of serotonin in the whole blood of schizophrenic patients. Since most blood serotonin is found in platelets, platelet counts were made on each sample to exclude the possibility that variations in blood serotonin were due to an alteration in platelet concentrations.

METHOD

Sixteen hospitalized chronic schizophrenic patients were studied (10 men and 6 women; mean age=27 years, range of 17 to 35 years). Diagnoses reflected a consensus of three psychiatrists. The control group consisted of 20 healthy volunteers (13 men and 7 women; mean age=29 years, range of 20 to 35 years) not receiving any medication. Venous blood was drawn between 8:30 and 10:00 a.m. into ACD solution (acid-citrate-dextrose, formula A, Becton-Dickinson Co.). Samples were immediately placed in ice and analyzed within four hours.

Platelet counts were made in a Coulter Counter, model B (Coulter Electronics, Inc.). Serotonin was extracted from 2 ml of blood (10); however, measurements of serotonin in blood extracts using 5-hydroxyindole native fluorescence were not satisfactory because of the low amount of fluorescence. Consequently, we used a modification of the *o*-phthalaldehyde (OPT) method (11) with the addition of cysteine (12). Separate blanks (OPT omitted) and internal standards were used for each sample. Individuals who performed the serotonin and platelet measurements were blind as to experimental designations of patients versus control subjects.

Repeated determinations were made over a period of at least two weeks to two months in 8 subjects as a means of investigating the stability of serotonin concentrations and platelet numbers over time.

Means were used when several measurements were made on the same control subject. All patients were first considered as one group and then divided into two groups according to whether or not they received drug treatment. When the patients were considered as a single group, grand mean measurements were used. In three of the patients, measurements were made in both drug-free and drug periods and the respective means are included in both groups. A two-tailed t test was used to evaluate any significant differences between groups.

Drug-free patients were off medication for three to five weeks before the collection of blood. Patients under drug treatment received various combinations of phenothiazines, amitriptyline, and, in most cases, small doses of trihexyphenidyl (Artane) or benztropine (Cogentin).

In an attempt to investigate acute effects of diet, we compared serotonin levels and platelet counts in three volunteers in a fasting state and one hour after breakfast.

RESULTS

In the three subjects in whom the acute effect of diet was studied, serotonin and platelet values did not differ significantly between the fasting samples and the samples taken after breakfast. These results confirm the experience of others (10, 13). Therefore, samples were taken

†Significantly different from control subjects ($p<.01$) and medicated patients ($p<.05$).

without regard to the fasting state. Serotonin and platelet content of blood were relatively stable in the same individual. In one subject five determinations were made over a period of two months, and mean serotonin and platelet values were 180 ng/ml (SEM=4) and 286 $\times$ 10^6/ml (SEM=5), respectively.

Whole blood serotonin was significantly higher in the patients considered as a single group than in the control subjects. As seen in table 1, mean whole blood serotonin was 186 ng/ml for control patients and 232 ng/ml for schizophrenic patients ($p<.05$). This difference remained significant when corrections for platelet counts were made. When the patients were divided into medicated and unmedicated groups, however, this difference was almost exclusively due to the very high levels of serotonin in the drug-free group. Also, mean whole blood serotonin was 298 ng/ml for the drug-free patients, compared with 199 ng/ml for the patients receiving psychotropic medications ($p<.01$). The patients on drugs did not differ from the control subjects. These differences are not explainable on the basis of age or platelet counts.

DISCUSSION

Our finding of high serotonin concentrations in the blood of drug-free schizophrenic patients is consistent with the previous observation that MAO activity is low in the platelets of such patients (7, 8). In order to determine whether these two conclusions are interrelated in a cause and effect manner, we must consider several factors in addition to platelet MAO activity. Blood or platelet serotonin concentrations are influenced by the rate of synthesis of the amine, its entry into the blood, plasma MAO activity, and the functional status of uptake, storage, and release mechanisms in the platelets. It is not known whether these factors operate normally in schizophrenia. Furthermore, serotonin is only one of the amines metabolized by the platelet MAO and is not, in fact, a very good substrate for this enzyme (13).

Another point raised by our results is the importance of the effect of medication. Serotonin levels were much lower (approaching control levels) in the medicated patients than in the drug-free group (table 1). The effect of drugs is not unexpected, since both phenothiazines (14) and tricyclic antidepressants (15–17) are potent inhibitors of the uptake mechanism of the monoamines in platelets and probably in the brain as well (17). Apparently, the effect of drugs counteracts any increase in serotonin due to reduced platelet MAO activity. Phenothiazines, however, do not appear to affect the activity of platelet MAO (3, 18). The effects of trihexyphenidyl and benztropine on whole blood serotonin are unknown because not enough patients were studied to control for these drugs.

The relationship between blood and brain levels of serotonin is unknown. Although the platelet has been proposed as a model for monoaminergic nerve endings (19), regulation of serotonin levels and turnover in the brain depends on the interplay of many complex factors and therefore may not parallel blood levels of the amine.

Two studies of blood serotonin levels in chronic schizophrenics reported low levels (3, 5), while two other studies found that serotonin was lower in chronic patients than in acute psychotics (4, 6). These latter two studies, nevertheless, disagreed because one (4) found that chronic patients had normal values, while the other (6) found that chronic patients had elevated values. However, these reports cannot be compared to the present study because they did not mention possible drug effects, age, matching, and platelet counts. On the other hand, our results are similar to the high serotonin levels found in the blood of children suffering from early infantile autism (13), a disease that is considered by some to belong to the schizophrenic nosological group.

Further studies will be required to determine whether blood levels of serotonin are influenced by nonspecific factors such as chronic hospitalization, diet, and psychological stress, or whether psychiatric patients with other diagnoses exhibit normal levels of blood serotonin.

Psychopharmacologic Management of Patients: A Method for Recording Treatment Decisions

BY DAVID J. KUPFER, M.D., AND THOMAS P. DETRE, M.D.

The authors describe a drug treatment form they designed, the KDS-8, that is suitable for use in all types of treatment settings. An important feature is a checklist of treatable target symptoms, with categories of improvement, no change, or worsening. Changes in drug regimen and the clinician's reasons for them are noted. Among the advantages the authors cite are easy retrievability of drug treatment data and the form's suitability for use in audit procedures and research.

THE MOVEMENT toward a new type of medical record that is easily accessible to various audit procedures and at least partially retrievable by automated methods has been considerably accelerated since the introduction of the problem-oriented system (1). However, the pace of these developments has been slower in psychiatry than in other medical specialties. Most psychiatric record keeping systems are still in an experimental stage (2–4), and those which have gained reasonably wide acceptance were designed primarily for hospitalized patients.

As we tried to retrieve data for retrospective studies of treatment efficacy, we became convinced that the current method of record keeping in psychiatric outpatient departments is simply a haphazard collection of statements entered in chronological order. Such records are supposed to be informative about the patient's condition, the treatment prescribed, and the evaluation of its effectiveness, but they do not fulfill any of these promises. On the contrary, despite the fact that an increasing number of patients receive drug maintenance therapy along with other supportive aftercare services, it is often impossible

Dr. Kupfer is Associate Professor and Director of Research, Department of Psychiatry, and Dr. Detre is Professor and Chairman, Department of Psychiatry, and Director, Western Psychiatric Institute and Clinic, University of Pittsburgh School of Medicine, 3811 O'Hara St., Pittsburgh, Pa. 15261.

The authors would like to thank Dr. Robert Byck of the Yale University School of Medicine for his assistance.

to determine why a particular therapeutic regimen was prescribed and what the clinician's reasons were for the frequent and often multiple changes that took place in the course of a patient's management. Having analyzed the clinician's tasks in making treatment decisions involving the use of drugs, we constructed a drug treatment form, the KDS-8. modeled along the lines of a problem-oriented record system. A reprint of the form is shown in appendix 1.

METHOD

One of our goals in designing the KDS-8 was to create a relatively independent chart component that would aid the clinician and others who might have contact with the patient or the record by providing a comprehensive overview of the following factors: 1) the patient's target symptoms, 2) the dosage of the drug(s) prescribed, 3) changes in treatment regimen, 4) the reasons for change, 5) side effects observed in the course of treatment, and 6) indications for and results of laboratory and diagnostic studies.

Clearly, whether the clinician is evaluating a patient who is a candidate for drug therapy or one who is already receiving psychotropic medication, his first task is to identify treatable target symptoms, since such symptoms are the reason for the initiation of drug treatment and serve as a test of the efficacy of the drug(s) prescribed. If the patient has been receiving psychotropic medication, the evaluation consists of determining whether the target symptoms have improved, remained unchanged, or worsened; it also notes whether there are any side effects and, if so, whether they indicate allergic or idiosyncratic reactions or are significant enough to require additional laboratory and diagnostic studies (which are likely to be ordered when the clinician judges the adverse effects to be out of proportion to the dosages administered). Studies may also be required when the prescribed drug tends to produce certain toxic effects that can best be monitored by biochemical or neurophysiologic tests as opposed to clinical observational methods, or when the drug in question must reach certain blood levels for optimal therapeutic effect (as may be the case with lithium).

The KDS-8 also gives the clinician an opportunity to spell out the reasons for his treatment decisions. Thus, whether he decides to continue the same drug and dosage, to increase, decrease, or stop the drug, or to prescribe an entirely new one, the relationship between treatment response and treatment decision can be clearly delineated. For instance, when the clinician believes that the patient's target symptoms have improved, he may (depending upon the course of the patient's illness and other clinical data) decide to leave the treatment regimen unchanged until he can determine whether the remission is stable. Alternatively, he may decide to decrease or even discontinue the drug(s) altogether. If the target symptoms have improved insufficiently or not at all, he might increase, decrease, or stop the drug, or try a new agent. Severe side effects may also lead to major changes in management, since the clinician may decide to prescribe a drug to control them (e.g., prescribing antiparkinsonian agents for extrapyramidal side effects), or he may decrease or stop the drug or prescribe another agent that is less likely to produce the same undesirable effects. A drug may also be discontinued when other drugs are being introduced in the patient's overall treatment regimen that are not compatible with it. Finally, a change in regimen may be required because of the patient's unreliability or the unavailability of other people to assume responsibility for administering the drug.

Space is also provided on the KDS-8 for entering all changes in the patient's condition or environment that may have a bearing on the overall management of the case (e.g., intercurrent nonpsychiatric conditions, suicide attempts, assaultive behavior, and changes in the patient's work functioning, relationship to family members, or other supports in the social environment).

DISCUSSION

The KDS-8 drug treatment form has been in use for two years in a variety of inpatient and outpatient settings and has proven to be superior to the highly individualized and imprecisely written entries usually recorded in the course of treatment. The clinician can at a glance obtain information regarding the drug treatment a patient is receiving, determine what the target symptoms are, and learn how the patient has been responding to a drug. In addition to improving the quality of care by making data easily retrievable, this form is also suitable for various audit functions, for large-scale studies of treatment efficacy, and for the surveillance of adverse effects.

Civil Liberties Versus Involuntary Hospitalization

BY STEPHEN RACHLIN, M.D., ALVIN PAM, PH.D., AND JANET MILTON, M.S.W.

The authors examine the issue of involuntary hospitalization for mental illness with particular reference to legal rights and civil liberties. Follow-up data of patients treated on a closed ward, as well as other available evidence, indicate that society is not ready for the abolition of involuntary hospitalization. The authors believe that the most fundamental right of the patient is that of adequate treatment, and therefore this should take precedence over an absolute right to liberty.

"WE SHOULD VALUE LIBERTY more highly than mental health, no matter how defined" (1). With this statement, made over a decade ago, Szasz issued a call for the abolition of all provisions for involuntary mental hospitalization. He went on to state that "no one should be deprived of his freedom for the sake of his mental health" (1). Thus began a campaign, in the name of civil liberties, to eliminate involuntary hospitalization. An organization of ex-patients, the Mental Patients Liberation Project, has dedicated itself to this end.

Bruce Ennis, the attorney who directed the Civil Liberties and Mental Illness Project of the New York Civil Liberties Union, has recently added momentum to the movement. He also has as his goal "nothing less than the abolition of involuntary hospitalization" (2). He believes that the standards for two-physician certification for commitment are ambiguous and questions their legitimacy. Feeling that "it makes no sense to put people in mental hospitals," he advised that they be shut down and all treatment be provided in the community.

Fischer and Weinstein (3) stated, "Psychiatry has no rival among medical specialties in its susceptibility to fads and its readiness to board the newest bandwagon." They cautioned us to avoid rushing in before strengths and deficiencies are appraised and not to allow our enthusiasm to impair our judgment, with the attendant consequence of losing the benefits of established ways.

It is our purpose in this article to examine the question of involuntary mental hospitalization from the standpoint of the profession, the patient, and the community, with particular reference to legal rights and civil liberties.

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

At the time this work was done, the authors were with the Williamsbridge-Fordham Unit, Bronx Psychiatric Center, Bronx, N.Y., where Dr. Rachlin was Chief of Service, Dr. Pam is Supervising Psychologist, and Ms. Milton is Psychiatric Social Worker. Dr. Rachlin is currently Deputy Director, Meyer-Manhattan Psychiatric Center, Ward's Island, N.Y. 10035. Drs. Rachlin and Pam are also Assistant Clinical Professors of Psychiatry, Albert Einstein College of Medicine, Bronx, N.Y., and Ms. Milton is Field Instructor, Hunter College School of Social Work, New York, N.Y.

PRESENT STATUS OF INVOLUNTARY HOSPITALIZATION AND PATIENTS' RIGHTS

The following statement describes, in part, the official position of the American Psychiatric Association on the issue of involuntary hospitalization of the mentally ill:

> Unfortunately, a small percentage of patients who need hospitalization are unable, because of their mental illness, to make a free and informed decision to hospitalize themselves. Their need for and right to treatment in a hospital cannot be ignored. In addition, public policy demands that some form of involuntary hospitalization be available for those mentally ill patients who constitute a danger either to themselves or to others. (4)

In an overview article, McGarry and Kaplan (5) reviewed the various state statutes related to admission. They noted the increasing use of voluntary admissions and the significant limitations on the wholesale use of the involuntary admission provisions as the standards for the latter become more stringent. Another important trend is the establishment, by law, of the right of the patient to legal representation.

Our own state of New York has a new mental hygiene law, which defines "in need of involuntary care and treatment" as the situation in which "a person has a mental illness for which care and treatment as a patient in a hospital is essential to such person's welfare and whose judgment is so impaired that he is unable to understand the need for such care and treatment" [NY Mental Hyg Law, Article 31, s 31.01]. The patient's right to a judicial hearing following involuntary admission on medical certification is assured, as is his notification relative to such a right. The maximum period for this type of hospitalization is 60 days.

The rationale in support of involuntary hospitalization has been described by Robitscher (6), who, citing Birnbaum, noted the right of the involuntarily hospitalized patient to receive adequate treatment in exchange for his being deprived of his liberty. The benefits of treatment enable the patient to regain his liberty at an early date and thus legitimize his hospitalization. Without this, the due process standard is not met, and the patient should be released. The right to treatment has been affirmed as a constitutional right, and it is the only justification for civil commitment.

EXPERIENCES WITH A CLOSED WARD

We worked as part of the treatment team on what was, at the time, the only locked ward at Bronx Psychiatric Center (formerly Bronx State Hospital). This intensive care unit (ICU) treated patients who had a special need for the added structure and setting of firm limits. Our patients were accepted on referral from the open wards if they were treatment failures because of repeated elopement, dangerousness to themselves or to others, or severely disturbed and agitated behavior. The utilization, problems, and advantages of the ward's program have been discussed in a previous paper (7). Because the ward door was always locked, the setting would presumably be considered offensive by most civil libertarians.

To answer the question of what happened to patients so treated, we undertook the present follow-up study. Each of the first 50 consecutively admitted patients (34 men and 16 women) completing a course of treatment in the ICU was used as his/her own control. A comparison was made between the one-year period prior to the index admission and the one year subsequent to first release from the ICU. Using the criteria of number of hospitalizations, interval between admissions, and total time spent as an inpatient, we were unable to demonstrate any statistically significant differences between the pretreatment and posttreatment years for the group as a whole. Similarly, we could not prove any marked reduction in the overall incidence of those behaviors that led to the original referral.

In studying the data, we were struck by the wide individual variability among the subjects. Therefore we rated each patient on a global basis, and we achieved nearly perfect agreement by consensus after reviewing all available records. Fourteen patients (28 percent) were considered to be improved. Of these, 5 were much improved in that they spent the entire follow-up year in the community and out of the hospital. The other 9 were hospitalized for portions of the year, but showed little repetition of the behaviors that led to their transfer to a closed ward. Almost half of our patients (N=23) showed little change in symptoms throughout most of the follow-up period. We rated 6 patients (12 percent) as worse. No useful ratings could be made for 7 patients (14 percent) because data were not obtainable, the usual reason being the patient's departure from New York.

Interpretation of the global follow-up ratings is difficult. It is, however, our feeling that the results are generally positive, since one must bear in mind that we were dealing with the most difficult-to-treat group of patients that could be selected. These individuals simply did not "make it" in the more usual treatment setting. For a fair number of them, their stay on the ICU interrupted or reversed a course of patienthood that had previously spiraled continually downward.

To directly relate our experiences to the main theme of this report, let us look into the reactions to closed ward treatment. It may be stated unequivocally that the community was strongly in favor of such a treatment modality and, at times, distressingly so. Not once in the two years of our study was there a complaint from any relative, group, or other interested party that we were locking up someone needlessly. Rather, the reverse was true. The pressure was clearly in the direction of treating more patients in the closed ward setting, and there were frequent requests from various individuals outside the hospital that patients be admitted to our ward.

We were confronted with the painful fact that the community does not understand, sympathize with, or want these individuals in its midst. Witness the following: In one case, persons representing themselves as spokesmen for an ethnically oriented social and political action group accompanied a patient to the admitting room of the hospital to assure her admission to a locked ward; they contended that she had thrown her newborn infant into a trash can on the street. Because of the nature of her behavior, and the social pressure, the patient was accepted for direct admission to the ICU. We later learned that the story was pure fabrication. The community had defined the patient as a nuisance, and it wanted to make sure that she stayed in the hospital.

In another instance, a young male patient arrived with several notes scrawled on the admitting papers sent from the community general hospital indicating that he was "to be admitted to a closed ward by order of Commissioner X [a name was given], New York City Department of Health." While we were under no obligation to heed these instructions, we did so. Within a day it was learned that no such commissioner existed. These examples illustrate the fact that community groups will go to great lengths, including subterfuge and misrepresentation, to rid themselves of the "troublesome" mentally ill.

As indicated in a previous report (7), our patients rarely objected to the locked ward, and when they did so, it proved to be an objection to being in the hospital rather than on a particular ward. A large number of the patients signed agreements to remain as voluntary patients with full knowledge of the fact that they would be kept on the ICU as long as the staff felt that it was necessary. In their discussion of the advantages of a closed ward, Fischer and Weinstein (3) stated, "In the readmission of former patients, there has not been one instance in 10 years in which the locked door was objected to by either the patient or his relatives." Our experience was essentially the same.

THE POSITION OF THE COMMUNITY

One of us (S.R.) served as chief of an open-door service at Bronx Psychiatric Center. In that capacity, monitoring the interface between hospital and community was one of his principal functions. The direction that families take is eminently clear. Whether they bring their requests to the ward staff, the chief of service, the director, or even the commissioner, it is their desire that the patients be kept in the hospital when we feel that they are ready for discharge to the community. Answering such complaints has become part of the daily routine of the

hospital staff. In cases where the family wanted to have its relative removed from Bronx Psychiatric Center, it was because of their objection to the open doors.

By no means are these family attitudes always, or even often, desirable. We mention this simply to point out that families cannot be overlooked in a cavalier fashion. They tell us something about societal misapprehension, capacity to tolerate deviance, and the tensions and problems of living with psychotics. If we plan to release a patient to his family, it behooves us to see to it that the environment to which he will return is not a rejecting one. We must recognize that the family also has certain rights and that these are not always compatible with having a seriously disturbed and untreated patient residing in the household.

In surveying community attitudes toward mental illness, Bentz and Edgerton (8) reported an important difference between the general public and the defined community leaders. Significantly fewer of the latter group believed that mental hospitals are needed to protect the community from the mentally ill (35 percent versus 70 percent of the general public). The public saw the protective aspect as a primary role of the hospital. These findings serve to remind us that what the most vocal members of society may be saying is not necessarily indicative of the grass-roots sentiment.

A look at what happened in California in 1973 may be enlightening. That state had announced plans to phase out its state mental hospitals within the next few years. A legislative committee investigating the possible impact of this decision heard complaints that the state laws, while designed to protect patients' civil rights, were then too liberal with regard to the release of potentially dangerous patients (9). There were also accusations that the hospitals were "dumping" patients into communities unprepared to care for them. The strength of public opinion resulted in the reversal of the decision to abolish state hospitals (10).

Aviram and Segal (11) detailed some of the mechanisms that communities are developing to continue to exclude their mentally ill in the face of current trends toward community-based care. They presented evidence that the penal code is increasingly used to commit patients for long-term care. "Ghettoization" and bureaucratic maneuvering were among the other techniques they discussed. They provocatively titled the final section of their paper "From Back Wards to Back Alleys."

Making a plea for a continuum of treatment facilities, Mosher and Gunderson forewarned us,

> First, it must be recognized that most people would rather not be confronted on a day-to-day basis with behavior that is defined as socially deviant; and one result of the community orientation of mental health care will certainly be increased contact with deviance. Furthermore, the patient's deviant behavior is likely to adversely affect his family's functioning and may cause considerable embarrassment. If we demand that families assume primary responsibility for the care of an ill relative, without provision for *their* needs, we can expect a backlash against our community-oriented efforts, and the voice of the average man in the street, who has also been discomforted by the deviant behavior of patients, will be added to the families' chorus unless we provide for *his* needs. (12, p. 48)

DISCUSSION

Critics of psychiatry will always be with us. They serve the useful function of forcing us to examine where we are, how we got there, and where we are going.

In this case, we do not deny the good intentions of those civil libertarians who advocate the abolition of involuntary hospitalization. There is, however, a critical danger to which we must not succumb. A few individuals set themselves up in an elitist fashion, pretending to speak for the masses as to what is right. They make their statements without first finding out what the public wants. Lives are affected thereby.

We believe that the weight of the evidence reviewed, both ours and that of others, clearly indicates that society is not ready for the abolition of involuntary hospitalization. Certainly the wholesale use of such a procedure is not tenable. However, even though there are abuses, this does not mean that we must throw out the baby with the bath water.

The humane approach to serious impairment of mental functioning demands that the suffering of the patient be relieved. He must be helped to take his place in society comfortably. We believe that this right is more fundamental than, and therefore takes precedence over, that of liberty, for without appropriate therapy what do we offer the patient? It is true that he is free to come and go as he pleases, but what about the quality of his life? Can we really call it "liberty" if someone walks the streets in terror because of paranoid delusions or threatening hallucinations? Or if he is at home and subject to constant barrages from a rejecting environment?

Involuntary hospitalization remains the procedure of choice for a small group of patients who are seriously mentally ill and unable to make an informed decision as to their need for inpatient care. Such a hospital admission is not forever, but rather for a finite period of time. The rights of such patients require protection in the form of judicial review. *The overriding right is that of adequate treatment.* When it is provided, we can assure a more meaningful liberty for the patient, his family, and the community. We cannot surrender to the temptation to uphold an absolute right to liberty and, because of it, abrogate or negate many others.

Brain Hypoxia, Minimal Brain Dysfunction, and Schizophrenia

BY H. ALLEN HANDFORD, M.D.

The author hypothesizes that individuals who suffer brain hypoxia prenatally, perinatally, or immediately postnatally constitute a population at risk for minimal brain dysfunction and for schizophrenia in adulthood. This hypothesis has implications for early intervention with children who have MBD and their families and for multidisciplinary management of these cases throughout childhood.

ON THE BASIS OF more than a decade of clinical experience with mentally ill children, including five years of research on early infantile autism (1), follow-up of these children extending into adulthood, and a review of the records of adult schizophrenics, I wish to propose a hypothesis developing from research focusing on brain anatomy and physiology. Simply stated, the hypothesis is that individuals who have survived prenatal, perinatal, or immediate postnatal hypoxia constitute a population at risk for the development of minimal brain dysfunction and, subsequently, of schizophrenia. A corollary of this hypothesis is that the type and age of onset of schizophrenia are determined within a system composed of the following factors: 1) the stage of brain development at which the hypoxia occurred, 2) the degree of hypoxia and related brain tissue damage, 3) the anatomic location within the brain (including brain stem) of the hypoxic effects, and 4) the patient's interaction with his family and social environment.

Dr. Handford is Clinical Assistant Professor of Psychiatry and Human Behavior at Jefferson Medical College, Philadelphia, Pa., and Chief Child Psychiatric Consultant at the Child Development Center, 1605 West Main St., Norristown, Pa. 19401.

The childhood disorder MBD, described by Strauss and Lehtinen (2) over 25 years ago, has gained increasing diagnostic, therapeutic, and educational significance in recent years. The manifestations of the disorder include impairment of social judgment, emotional lability, poor coordination, perceptual disability, and related learning problems. The functional disability of such patients ranges from mild to severe, and they require many modalities of therapeutic and educational intervention during childhood and adolescence. Moreover, as is shown in the following case report, these patients may be at risk in adolescence for the development of schizophrenia.

Case 1. Ms. A was a 21-year-old single woman who had been referred first at the age of 13 because she was "flapping about the school ground acting like superman." The clinical picture was one of borderline intelligence, impaired social judgment, and slow learning, with occasional poor reality testing. Her birth was premature, and oxygen was required during the first five days. Her development was slow but progressive during childhood, and she maintained an IQ of about 80. At age 17, she began having periods of decompensation, characterized by crying out in the night, extra sensitivity to voices, ideas of reference, and misinterpretation and fear of certain colors, graffiti, and designs. She expressed the delusion that she had aborted a fetus into the toilet at home. She had been diagnosed in early childhood as having nonpsychotic organic brain syndrome (MBD) secondary to prematurity. In adolescence, her symptoms strongly suggested a schizophrenic process.

The question of brain tissue damage in MBD has been a controversial one. Recent studies appear to have confirmed the existence of such damage, localized the brain areas affected, and isolated an important causal factor, brain tissue hypoxia, in both MBD and schizophrenia.

FETAL AND NEONATAL BRAIN SECTION STUDIES

In 1970, Towbin (3) reported clinical histories and autopsy material from over 600 live and stillborn infants. He preserved focal lesions by whole-brain histologic sectioning and consistently demonstrated their geographic relationship in the brain. He described four main types of central nervous system damage in the fetus and newborn: subdural hemorrhage, spinal cord and brain stem damage, hypoxic cerebral periventricular infarctional damage, and cerebral cortical infarctional damage. All of these but the first were implicated in the etiology of subsequent MBD or classic cerebral palsy.

According to Towbin, spinal cord and brain stem damage due to direct but often undetected birth trauma was responsible for most of the signs of neonatal distress determined in the delivery room or newborn nursery by the Apgar score. This is the case because the Apgar factors—initiation of respiration, sustained cardiac function, muscle tone, and irritability—depend on the intact functioning of the brain stem and upper cord structures. Traumata that contribute to such damage are breech delivery, forceps traction, prematurity (with the attendant difficult passage of a small infant through an unripe birth canal), first birth, and precipitous delivery. Respiratory depression from such direct damage produced sufficient hypoxia to cause cortical infarctional damage in term infants and to cause periventricular damage in premature infants.

Towbin reasoned that the differing sites of damage in term versus premature infants depended on the site of the neuronal germinal matrix, the area of the most rapidly developing neural tissue at any given time. He observed in his sections that this was where the blood supply was most diffuse, fragile, and prone to infarctional episodes secondary to hypoxia. The germinal matrix in the term infant from the 35th week of gestation through delivery and postnatally is in the cortical areas. Towbin noted that when damage occurred, it was histologically most evident in the Betz cells of the precentral cortex and the Purkinje cells of the cerebellum. Betz cells mediate motor function and Purkinje cells mediate coordination. Malfunction in these areas is consistent with two of the classical signs of MBD, impaired motor function and poor coordination. More severe classic cerebral palsy, with spasticity, ataxia, or athetosis indicating involvement of the basal ganglia (in the periventricular area), suggests hypoxic damage at an earlier stage of brain development.

In the Towbin series, premature infants of 28 weeks gestation were the most prone to develop the deep periventricular infarctional damage, since the greatest germinal matrix development at that time was in the periventricular area. Structures affected were the corpus striatum, basal ganglia, and thalamus. Conditions producing hypoxia prior to actual birth included partial placental separations (indicated by bleeding near the end of pregnancy) and shunting phenomena of the vascular supply system, seen in as many as 70 percent of monozygotic twins (4). These factors help to account for the various forms of brain damage that occur even when the actual delivery is uncomplicated and for the fact that the premature infant is at greater risk for such disability.

This evidence from fetal and neonatal studies strongly suggests the validity of the concept of structural as well as functional damage to brain tissue in MBD as well as in classic cerebral palsy. This theory awaits corroboration from histologic analysis of postmortem brain specimens, correlated with clinical histories of children of various ages.

BRAIN HYPOXIA AND SCHIZOPHRENIA

In 1973, Campion and Tucker (4) seriously challenged one key basis for the genetic hypothesis of the etiology of schizophrenia—i.e., the increased concordance for the disorder in monozygotic (MZ) twins as opposed to dizygotic (DZ) twins and singletons. In the process, they reviewed convincing evidence in support of the brain damage theory of the origin of schizophrenia. Citing anatomic, physiologic, and developmental data on MZ and DZ twins, they pointed out that, contrary to previous belief, the prenatal environments of MZ twins are not identical. Approximately 70 percent of MZ twins share a single chorion and are therefore subject to the intermittent reduction of blood supply to one fetus or the other, a phenomenon known as "transfusion syndrome." This may be so severe as to cause significant degrees of brain damage. Singletons, DZ twins, and 30 percent of MZ twins are not so affected because each has a separate chorion. It is worth noting that the concordance rate for schizophrenia in MZ twins is approximately 70 percent as opposed to the 100 percent rate that might be expected if MZ twins were environmentally and genetically equal. According to Towbin (3) this shunting is at fault in cortical infarction found in near-term twins. Campion and Tucker provided substantial evidence that MZ twins are at far greater risk than are DZ twins or singletons for disparities in intellectual development, congenital malformations, low birth weight, and infant mortality. They further maintained that perinatal complications and subtle neurologic damage are either part of the development of schizophrenia or essential elements of the disorder itself. Without the corroboration of the twin studies, the case for a genetic basis of schizophrenia is greatly weakened.

In an extremely complex analysis of anatomic and neurobiochemical data relating to parkinsonism and schizophrenia, Stevens (5) concluded that the characteristic symptoms of schizophrenic patients—preemption of consciousness by fear, a sense of unreality, and heightened or distorted sensory and sexual perceptions of an acute or chronic nature—are related to the excess production of, or increased sensitivity to, dopamine released locally from the dopaminergic pathways at the principal terminus of the dopaminergic system, the limbic striatal portion of the corpus striatum. Consistent with our previous conclusions, Stevens indicated that this could occur secondarily to damage and malfunction of the pathways from hypoxia, infection, or other injury. As further confirmation of aberrant brain function in schizophrenia, she

presented EEG data from nonepileptic schizophrenic patients recorded during periods of deranged mental activity or distraction by endogenous percepts (as evidenced by stereotyped behaviors and hallucinosis). These EEGs indicated abnormal potentials in the subcortical striatal areas. She concluded that there seemed to be a pathologic widening of consciousness in schizophrenic patients, characterized by an intensification of both endogenous and exogenous perceptions. This intensification generated the clinical state of disorganizing anxiety and irrational behavior. A key preliminary element in the treatment of schizophrenia would be pharmacologic agents such as the phenothiazines or butyrophenones, which directly affect dopamine metabolism at the pathway terminus and thereby narrow the field of consciousness to manageable proportions. This enables the patient to cooperate more effectively with nonpharmacologic life management programs.

CONCLUSIONS

The importance of recognizing a possible link between pre- and perinatal brain hypoxia, MBD, and schizophrenia through damage to the dopaminergic pathways cannot be overemphasized. The implications of this concept range from improvement of prenatal care and refinement of obstetrical techniques, through early intervention with developmental programs for infants at risk and their families, to multidisciplinary management of the child with MBD, including appropriate medication throughout childhood. The awareness that such children are handicapped and at risk for schizophrenia is of epidemiologic significance in delineating more clearly a target population for research and early case finding. Dynamically, so-called schizophrenogenic parents or families could be counseled in the more reality-based framework of understanding feelings toward such children and learning to cope with their affective and cognitive problems rather than focusing upon a dubious concept of parental causality, with its strong guilt-evoking overtones.

I am currently taking such an approach in collaboration with a multidisciplinary team consisting of a pediatrician, psychologist-educator, audiologist, pediatric neurologist, and special education teachers working with some 80 at-risk nursery school children and their families in a community-based child development center. Data gathering and analysis over a significant time span remains to be accomplished, but early indications of affective and cognitive development in the children and improved coping ability in their parents seem promising. In our program, attention is being paid to the subtle neurologic deficits with corrective medication, special developmental educational approaches, and parental counseling. This model of early intervention, based on the gradually developing concept of the neurophysiologic origin of schizophrenia, seems to offer new hope for the alleviation and even prevention of this enigmatic affliction.

The Educational Process as a Treatment Modality in a Drug Rehabilitation Program

BY LEONARD SUCHOTLIFF, PH.D., AND SUSAN MEYER, M.A.T.

The authors describe an educational program that is an integral part of a residential drug rehabilitation program. They believe that effective treatment of drug addiction must provide individuals with the opportunity to acquire skills that will make it easier for them to compete in the job market when they leave the program. They discuss how the educational process serves as a treatment modality that supplements and complements the other aspects of the therapeutic community.

THE BASIC PREMISE of the Edon House long-term (14- to 18-month) residential drug rehabilitation program is that participation in a therapeutic community is not enough to help someone stop using drugs. Effective treatment must provide individuals with the opportunity to acquire skills that will make it easier for them to compete in the job market when they leave the program.

One of the major deficiencies noted in at least half of the addicts who have entered Edon House is that they have not completed high school. In order to meet this need, an educational program geared toward providing educational enrichment was initiated. Since its inception approximately two years ago, 65 residents have been prepared to take the General Equivalency Diploma (GED) examination; 55 residents have passed.

What makes the educational program at Edon House unique is that it is an integral part of the therapeutic community. The educational program is viewed as a treatment modality that supplements and complements other aspects of the program. In most therapeutic communities, educational achievement, if stressed at all, is seen as a peripheral activity that takes place outside the unit (e.g., adult education classes). Volunteer teachers whose services are isolated from other areas of the program are also sometimes used. In either case, educational achievement is encapsulated from the rest of the resident's life within the therapeutic community. It is usually seen as having little relevance beyond its functional utility ("You need an education to get a good job").

At Edon House, the resident's participation in the educational program is given equal weight with his participation in groups, job functions, and seminars. Education is seen as a particularly significant area not only because it is functionally useful to the resident but also because the very process by which the individual learns and the experiences he encounters in the school are therapeutic. The major aim of this paper will be to briefly describe the educational program at Edon House and to point out how the educational process and the therapeutic process complement and supplement each other.

At the time of the study the authors were both with Edon House, Fairfield Hills Hospital, Newtown, Conn. 06470, where Dr. Suchotliff is Director and Ms. Meyer was Educational Director.

THE EDUCATIONAL PROCESS AS THERAPY

The educational program at Edon House is designed to meet as many of the diverse needs of the resident population as possible. At present, the program features five key areas: the reading laboratory, GED classes, remedial- to college-level mathematics classes, precollege classes and various educational enrichment classes, and craft and vocational skill classes. Individual tutoring is also available.

The education department consists of a director whose area of specialization is English, a reading specialist who is in charge of the reading laboratory, and program residents who conduct mathematics classes and individual tutoring. Both the educational director and the reading specialist also conduct treatment groups and participate in daily case conferences. The job function of the tutoring residents within the house is that of schoolroom assistant. The educational director is responsible for the coordination of the school program with other aspects of the therapeutic community. The student residents, tutoring residents, and teaching staff are all members of the therapeutic community.

Residents attend classes on a voluntary basis. Once a commitment to a class has been made, however, the resident is held responsible to honor his obligation. A commitment is defined as extending from six weeks to two months, depending upon the course of study involved. At the end of this period, the resident decides whether or not he will renew his commitment and continue to attend classes. Since the Edon House school program represents a "last-ditch" chance at education for many residents, attendance is not a problem; the school is supported enthusiastically.

Every student enrolled in the educational program is evaluated individually in order to determine his particular level of reading speed and comprehension. A specific program of study is then mapped out to meet his needs.

This assessment forces the resident to confront his educational limitations directly. All the cunning and manipulative skill that were useful on the street are worthless here. The resident to whom educational achievement was not a relevant factor in determining his self-worth and status when he was using drugs must now readjust and evaluate himself and his position vis-à-vis others in terms of his ability to learn.

In the educational laboratory, where we use preprogrammed reading material and audiovisual machines, the student proceeds through the course at his own speed until he achieves his desired level of competency. Accurate responses are reinforced and errors are corrected immediately so that the student's primary experience is one of success.

In school more than in any other area of the program, goals and expectations are clearly defined; the resident gets continuous feedback on his progress and has a definite and objective barometer of success. In other areas of the program, he may fool himself and others by simulating concern, but in the educational program he cannot do this because progress is objectively definable. We have found that educational assessment and participation in the reading laboratory, which confront the resident with a clear picture of his own educational level, are the best image breakers available. They literally force the addict to acknowledge his deficiencies and to place himself in a situation where he is a learner who must depend upon others in order to get what he needs.

Changing the Hierarchical Structure

The structure of almost all therapeutic communities is hierarchical (1). Status in the program is generally based upon the resident's job in the house and how long he has been in treatment. A major advantage of the educational program is that it places individuals of differing status in the rehabilitation program in situations where their position in the hierarchy is not a relevant variable. Competency thus comes to be redefined in terms of educational achievement. An individual's progress in school becomes critical in determining his progress within the house. The resident's participation, his motivation, and his attitudes in school are communicated to the whole staff and are dealt with as any other behavior would be. In many cases treatment plans have been worked out whereby individuals have been assigned to certain courses or given positions of responsibility in the education department in order to work on areas of deficiency or to get positive reinforcement in areas of particular expertise.

In school we find such situations as residents who were considered more advanced depending on those thought to be less advanced, strong residents depending on meek residents, and men depending on women. In short, school undercuts the implicit assumption of therapeutic communities that the longer one is in treatment, the more competent he must be in all areas. In addition to imparting skills, the educational program clearly forces the resident to deal with social situations that he might not encounter in other areas of the program.

After a resident has successfully completed the reading laboratory, he may enroll in a class geared toward preparing him to obtain a GED. These classes are small; students are given instruction in grammar, literature, social studies, science, and mathematics. Intensive classwork is done for approximately two months. At the end of that period, those students considered sufficiently prepared may take the test for an equivalency diploma.

The Experience of Success

As the individual resident progresses in the educational program, he is not only achieving mastery over the material, which makes him feel more competent, but he is also mastering a skill valued by "straight" people. For many addicts the passing of the GED is their first concrete experience of success in the "straight" world. Residents who have successfully completed the GED express the view that their ability to complete school, something that previously turned them off, indicates that they may now be capable of dealing with other situations they had previously felt unprepared or unable to handle. It may be speculated that a correlation exists between success in school and the ability to complete the program and remain drug free.

For those residents who enter the program with high school diplomas, and for those who obtain them while at Edon House, precollege and various educational enrichment classes are offered. In addition, a Scholastic Aptitude Test course is given that prepares the resident to take that examination.

A relaxed and informal atmosphere prevails in these classes as well as in the reading laboratory. Residents are encouraged to be highly verbal, to do their thinking aloud, and to feel sufficiently at ease to make mistakes without the fear of being thought stupid. We foster the attitude that making mistakes is a natural and necessary part of the learning process, not a sign of weakness or a cause for embarrassment. Smooth talking for the purpose of manipulating others, however, is discouraged because this represents an attempt to hide one's ignorance. Only when a resident feels free to reveal what he does and does not know can true learning be initiated.

We would note the similarity between the educational philosophy and the underlying philosophy of the therapeutic community: both encourage the individual to redefine his concept of strength from one of being able to handle all situations adequately and without assistance to allowing himself to make mistakes and learn how to ask others for help. The ultimate goal of education and of therapy is to teach a method of problem solving that the individual can employ in new situations.

DISCUSSION

This educational program is predicated upon the philosophy and spirit that underlie all phases of the therapeutic community: commitment to change and the acceptance of responsibility. The value of a school program lies as much in its usefulness as a therapeutic tool as in its functional utility. It encourages the addict to confront his

strengths and limitations realistically and provides opportunities for him to experience success and develop feelings of self-esteem. The process of learning, whether it focuses on mastering unfamiliar subject matter, acquiring new skills, or understanding one's own behavior and redefining oneself in relation to others, is therapeutic; the therapeutic process is educational. The functional results of education, the techniques used in the school program, and the very nature of the learning process itself allow a treatment modality and dimension of rehabilitation unavailable to therapeutic communities that do not have such a program.

Translating Despair

BY JAMES E. SABIN, M.D.

The author reviews two cases of suicide by Spanish-speaking patients who were evaluated and treated by English-speaking psychiatrists using a translator. He suggests that the patient's emotional suffering may be selectively underestimated when the clinician works by means of translation. The diagnosis may emphasize psychotic features of the illness and minimize the affective component; consequently the risk of suicide may be underestimated.

WITH THE DEVELOPMENT of community mental health centers and comprehensive neighborhood health centers, many of which serve Spanish-speaking populations, it is increasingly common for English-speaking mental health professionals, using translators, to evaluate and treat Spanish-speaking patients. Communicating in a common language would obviously be preferable, but the size of the Spanish-speaking population and the current dearth of Spanish-speaking mental health professionals make the use of translators a necessity.

The various techniques of clinical psychiatric evaluation have been developed in settings in which patients and clinicians, however different from each other, speak the same language. Speaking metaphorically, we say that the middle-class white clinician and lower-class third-world patient "don't speak the same language," but while the metaphor points to something real, it is a different form of noncommunication than occurs between the same professional and a Spanish-speaking patient. In medical terms, communication is a major instrument of clinical examination, and if the patient is using a second language or speaking through a translator, the instrument is altered and may produce altered results. For this reason, whatever method of evaluation an English-speaking practitioner may use, he cannot rely on it with the same assurance when he is working with patients who speak a different language. Similarly, the physician must adapt his ear to a new stethoscope before he can be confident in auscultation of the heart.

There is as yet no agreement as to how different languages in patient and clinician affect clinical evaluation, but there is clearly a pronounced effect. In a recent report Del Castillo (1) suggested that the bilingual patient may show less psychotic symptomatology when examined in English than when examined in his native tongue. He speculated that the mental effort required to speak in a second language puts the patient in better contact with reality and masks the psychosis that is apparent when the patient is interviewed in his language of origin. Marcos and associates (2), in an experimental study, reached the opposite conclusion, that "Spanish-American patients are consistently rated as showing more pathology when they are interviewed in English" (p. 552). The authors hypothesized that problems posed by speaking a second language produce changes suggestive of more pathology in the patient's clinical presentation and that a frame of reference applicable to native English speakers may not be valid when applied to an English interview with a native Spanish-speaking patient.

While differing in important details, these studies conclude that the bilingual patient appears different when examined in English than when examined in his native tongue. The differences noted are predominantly differ-

Dr. Sabin is Director, Community Mental Health Service, Massachusetts Mental Health Center, 72-76 Fenwood Rd., Boston, Mass. 02115, and Instructor in Psychiatry, Harvard Medical School, Boston, Mass.

ences in degree of psychosis (patients appearing more or less ill when examined under varying linguistic conditions). In principle it seems likely that altering the linguistic instrument may bring about apparent differences in kind of illness as well as apparent differences in degree of illness. I believe that the following cases illustrate the effects that translation can have on clinical evaluation.

CASE REPORTS

I have recently had occasion to review two cases in which Spanish-speaking patients evaluated by English-speaking psychiatrists in collaboration with a translator committed suicide. While both cases appear to reflect careful, responsible work, it is clear in retrospect that at several points different psychiatrists systematically underemphasized the affective component of the illness, with consequent underestimation of suicidal risk. Both patients were perceived as seriously ill (degree of illness), but the component of psychotic thinking was given undue prominence in the clinical evaluation at the expense of full recognition of the patients' despair (kind of illness). In describing the cases I have altered nonessential details.

Case 1. Ms. A., a 45-year-old South American woman, came to the United States when she was 30. Shortly thereafter she became pregnant and delivered a retarded son, with whom she lived in symbiotic intimacy. In the 18 months before she committed suicide she had four brief voluntary hospital admissions for what was diagnosed as a schizo-affective illness. The admissions were associated with events implying potential separation from her son and were characterized by crying, sadness, terror that she would be harmed or die, feelings of helplessness, and a wish to be cared for. Each time she responded rapidly to hospitalization and phenothiazine medication and was returned to outpatient care.

On the evening of her suicide a Spanish-speaking worker brought her to the hospital for evaluation of another decompensation, again in the context of threatened separation from her son. The worker was concerned because Ms. A. had spoken of suicide if she lost her son. Ms. A. was interviewed for more than an hour by the emergency room psychiatrist, who found her to be anxious and depressed. Ms. A. was offered a voluntary admission, but this time she declined hospitalization.

Despite the report that she had spoken of suicide earlier in the day, the emergency room psychiatrist judged her to be "not homicidal or suicidal now" on the basis of an extensive interview. Since Massachusetts law requires direct evidence of homicidal or suicidal trends for involuntary admission, involuntary commitment was not sought. Later that night she hanged herself.

Case 2. Mr. B., a 71-year-old former businessman from Puerto Rico, came to the mainland six years before his death. Following a physical illness he had developed a protracted psychotic depressive reaction characterized by intense fearfulness, delusional jealousy, sleep disturbance, and loss of his customary joie de vivre. He was treated intermittently at a general hospital for one year with a variety of medications, but with only limited benefit. His case was transferred to a neighborhood health center, where review of the case revealed he had not had an adequate trial of tricyclic antidepressant medication.

The patient and his family approved a plan for an initial course of tricyclic medication, followed by ECT if the medication were ineffective. Both Mr. B. and his family were opposed to hospitalization, which was offered. On the day of his death he slipped away from a sister who was watching him and hanged himself.

The family had been aware that Mr. B. was hopeless and wished to die; therefore, they had maintained a careful watch over him on their own initiative. The psychiatrist recognized that Mr. B. suffered from a severe psychotic depression, but he did not appreciate the extent of his despair and suicidal drive.

In neither of these cases was the individual or his family secretive about the presence of a serious illness. The translator in both cases spoke Spanish as her native tongue, was fluent in English, and had had training in school counseling. In case 1 she served as a supportive caseworker as well as a translator. In case 2 she saw Mr. B. only with the psychiatrist and did not have an independent relationship. Reviewing the cases she felt she had communicated her understanding of what the patients and their families said. As documented by the record, she brought Ms. A. to be evaluated on the night of her death out of an explicit concern that Ms. A. was considering suicide. In both cases the psychiatrists were well trained (two third-year residents in case 1 and a board-certified staff psychiatrist in case 2) and recognized that the patients were severely ill. In both cases the psychiatrist responsible had made home visits with the translator as part of the diagnostic evaluation; it did not appear that either psychiatrist was averse to working with Spanish-speaking patients. However, while all three psychiatrists diagnosed major mental illnesses requiring active intervention, none recognized the depth of despair and intensity of conscious suicidal feeling in Ms. A. or Mr. B.

A HYPOTHESIS

While two cases can at best only suggest a hypothesis, perusal of the notes kept during the course of treatment by the three English-speaking psychiatrists are consistent with a process I call "transformation of the familiar into the mysterious." In clinical terms this means emphasizing the features of psychosis (thought disorder, bizarre behavior) at the expense of observations pertaining to affect (sadness, loss of hope, despair). This process is illustrated clearly by the conclusion in the "present illness" section of the first admission note for Ms. A., written 18 months before her death.

> Ms. A. got angry, felt alone, unloved, and abandoned.... On Sunday evening and Monday morning she felt upset, was talking to herself, was disoriented, confused, feeling lonely and depressed and at times like hurting herself. She reportedly at one point attempted to choke herself. Because of this *bizarre behavior* [her friend] brought her to the hospital [italics mine].

The multiple references to a disturbed emotional state, culminating in description of a suicidal gesture, are misleadingly summarized as "bizarre behavior." The behav-

ior, all too comprehensible in the light of her ultimate suicide, was surely interpretable as a reflection of Ms. A.'s feeling of hopeless despair. The English-speaking clinician distanced himself from an evocative picture of Ms. A. by categorizing the clinical presentation as "bizarre."

A similar process is reflected in the note written 18 months later by a different psychiatrist (the emergency room officer who evaluated Ms. A. just before her suicide).

> She says she will die [if she could not have her son] but I cannot elicit a specific suicidal plan . . . she is not suicidal now. . . . Psychotic decompensation is likely in the event custody of Ms. A.'s son is taken from her.

The psychiatrist was acting under Massachusetts law in presenting evidence pertaining to involuntary commitment—in his judgment Ms. A. was not acutely suicidal. Ms. A.'s statement that she would die if she lost her son was interpreted as a sign of psychotic thought, not as an expression of despair ("I can't live without him") or of suicidal intent ("If I lose him I will die—by my own hand"). The emergency room psychiatrist, like the admitting psychiatrist one and a half years earlier, emphasized psychosis at the expense of fully recognizing Ms. A.'s affective state.

Mr. B.'s record contains numerous references to his anxiety, sleep disturbance, jealousy, and suspiciousness but never to his hopelessness or his despair. On reviewing the case after Mr. B.'s suicide the psychiatrist recalled that the translator had told him that Mr. B.'s family thought he was tired of living and wanted to die. This information, however, had somehow not guided his empathic sense of Mr. B.'s condition. The family had not denied his despair and suicidal potential, although Mr. B. ultimately thwarted their caretaking efforts (as can happen even in the hospital care of a suicidal person). The psychiatrist in the case, however, had unwittingly and uncharacteristically denied this particular aspect of Mr. B's illness.

More than 200 years ago, the philosopher David Hume observed in *A Treatise of Human Nature* (3) that empathic recognition of the emotions of another person is keen when the persons are close and dim when they are distant.

> The sentiments of others have little influence, when far removed from us, and require the relation of contiguity, to make them communicate themselves entirely. The relations of blood . . . acquaintance . . . education and custom . . . when united together, convey the impression of consciousness of our own person to the idea of the sentiments or passions of others, and *makes us conceive them in the strongest and most lively manner* [italics mine]. (p. 318)

Consistent with Hume, Schwab and associates (4) found in a recent study of medical inpatients that while amount of depressive symptomatology was inversely related to class, the presumably middle-class medical staff "is prone to ignore depression in lower-class patients" (p. 537).

In the bilingual situation the English-speaking mental health worker comes into intimate linguistic contact with the translator but not with the patient. When clinician and translator collaborate well, as appeared to occur in these two cases, there will be abundant data. However, the despair that I believe was an important part of the experience of Ms. A. and Mr. B. was not adequately appreciated by the English-speaking psychiatrists. Loss of hope and wish for death in another person is deeply painful to behold and resonate with—perhaps especially so for a health professional, whose work is so dedicated to the maintenance of life.

My hypothesis is that while translation allows transmission of data that promote diagnosis of psychosis, it may not reduce interpersonal distance enough to facilitate vivid appreciation of the patient's affective state. Because three separate clinicians (two psychiatrists with Ms. A. and one with Mr. B.) made the same clinical error independently of one another, I suggest that a tendency to avoid the pain entailed by recognizing another person's despair is abetted when clinical examination is done via translation. Because the clinicians showed good capacity to empathize with their English-speaking patients, ineptitude is not an adequate explanation, and because the process of underestimating affective pain was so similar in each case, a specific countertransference was not likely to have been operating.

CONCLUSIONS

Given the potential risks involved in underestimating the affective components of the patient's condition even while recognizing and responding to other components of the illness, I propose that mental health clinicians and their translator colleagues take special precautions. We should recognize that while translation allows effective gathering of data on life history and behavior, allowing recognition of psychotic phenomena, the process may selectively mute our recognition of the patient's despair. This leaves us with a picture of a sick person afflicted with an illness but not with the more accurate perception of a hopeless person, hating life, and moving toward choosing to end it by suicide.

LETTERS TO THE EDITOR

Journal Shredding Strikes a Responsive Chord

SIR: Thomas Gutheil, M.D., in "Rapid Retrieval of Literature for the Practicing Psychiatrist: A Practical Approach" (October 1974 issue) noted the difficulties in constructing a usable filing system and proposed a system using an index determined by individual interests. However, there are major problems in this approach in developing appropriate subject headings and in cross-referencing.

Fuller (1) described an alternative approach based on a numerical system with all cross-referencing done within the index. Textbooks in the physician's field(s) of interest are selected for the quality and clarity of their indexes, and a reference index is constructed by assigning a number in sequence to each textbook topic. Each article to be filed is given a number from the index and placed in the file folder bearing that number. Decimals can be used to expand each topic, making the system adaptable to changing interests.

This indexing method has been used successfully to file as many as 45,000 articles, including lecture and conference notes, photostats, and reprints. It has the advantage of being infinitely expandable, flexible, and readily cross-referenced, and it is applicable to the approach suggested by Dr. Gutheil.

JOHN M. RAINEY, JR., M.D., PH.D.
Detroit, Mich.

SIR: I have maintained a file such as Dr. Gutheil described for about nine years. While categorization is the very basis of logic and the joys of filing are many, the problems of riddance are increased when one superimposes one's own order on the mass of psychiatric data. My file now occupies two four-drawer file cabinets and appears to be growing exponentially. Articles from newspapers and magazines find their way to rest under my forever-subdividing subject headings, and the file is marvelous for collecting material for articles one hopes to write some day, ideas for projects, etc. I would suggest the following caveats to Dr. Gutheil and to his readers starting out:

1. Old journals can be thrown away, but old files become classics that represent work and personal interest and should not be discarded.

2. Start with no file headings, just a pile of blank folders and some folding envelopes to put them in. You'll soon expand, but think small as long as possible.

3. As soon as you receive journals, tear out the one or two articles that warrant keeping. It is utter folly to shred and file whole issues—that's what libraries are for. Also, most articles are back-to-back with other articles, necessitating dilemmas of choice or of duplication.

4. Let your choices of classic articles dictate your own system of classification. Use subdivisions only as files grow too large. A general title, e.g., "Quackery," to cover all that you disapprove of but need to know about is useful at times. Keep a separate smaller file of nonpsychosomatic titles from medical journals (if you must) and throw it all away every three years.

5. Since limiting my file to two cabinets, I have discovered that getting rid of old files is extremely painful, if not impossible. To do so, I pull out some of the thickest offenders, give them a number, e.g., Law 1, and start a new file, Law 2. I then put the file numbered 1 in a box in a closet or in professional storage. If you have no recourse to these files in two years or so, they may be destroyed. Don't start a second file if the subject seems to be played out. Classic papers must be kept forever, but they can be weeded out when you have recourse to them for lectures. (Psychoanalytic journals are not easily torn apart and need not be filed. They are only quarterlies and may be kept for five years, then donated to a psychiatric library.)

6. Never tear up journals in which you have published articles. Keep special shelves for those issues, or tear up only the extra complimentary copy the editor sends you.

Interested readers who wish to learn how I miniaturized my process-note-keeping system and how I cured a recalcitrant stamp collecting habit may contact me. Please don't send complimentary reprints as an introduction.

DAVID V. FORREST, M.D.
155 West 68th St.
New York, N.Y. 10023

SIR: I have been using the device of journal shredding Dr. Gutheil described for many years. I use the numbering system in the table of contents of Freedman and Kaplan's *Comprehensive Textbook of Psychiatry* (1) as the basis of my index, assigning numbers to articles and creating new headings as needed. I mark the index number in the upper right corner of the first page of the article and the date of publication in the upper left. My file clerk then shreds the journal and files the article chronologically in the appropriately numbered folder. I can then retrieve the article by referring to the headings in my index and pulling the numbered folder.

However, the process of assigning numbers and cross-referencing takes a considerable amount of time. Consequently, my system chronically runs behind my good intentions, and I would predict that most people would have a similar problem with Dr. Gutheil's system.

If the authors of *Journal* articles were requested to assign topic headings, cross-references, and numbers to their articles in the manner I have described, my file clerk could "shred" and file the *Journal* without waiting for my input and my system would not be delayed for my most important journal.

Two more steps would make the "information explosion" more manageable. First, it would help if the *Journal* staff were to assign topic headings, cross-references, and numbers for issues within the last 10 years. Finally, and most importantly, perhaps the success of this endeavor might convince the editors of the remaining 39 publications I receive to use the same system so that their publications could be filed in similar fashion.

As an individual who obviously suffers from a hopelessly incurable variant of bibliomania, I must confess that contemplating the implementation of this system sends me into raptures.

Editor's Note. We are most interested in these suggestions and proposals, and our staff is currently investigating the possibilities mentioned by Dr. Sones for facilitating literature retrieval. We would welcome further suggestions.

A Defense of the Nonmedical Model

SIR: I feel that the models presented by Frank M. du Mas, Ph.D., in his article "Medical, Nonmedical, or Antimedical Models for Mental Health Centers?" (August 1974 issue) are outdated and, in many ways, inaccurate and misleading.

Dr. du Mas states that group characteristics for nonmedical personnel are as follows: less ability than M.D.s, less rigorous selection, greater heterogeneity, less formal education, less rigorous training, and less scientific training than M.D.s. I think this journal has shown ample evidence that these characteristics do not apply to the Ph.D.s or M.S.W.s who have written for it. As regards training procedures, virtually all Ph.D. candidates must write dissertations in order to demonstrate research ability, whereas M.D.s generally do not. The point is that a Ph.D. has much formal and scientific training, although it is often different in kind from that of M.D.s.

Dr. du Mas states "By law and training they [M.D.s certified in psychiatry] are the only ones qualified to treat the whole person: with drugs, organically, surgically, psychologically, and socially." What other person is there but the whole person? It is absolutely untrue that qualified and licensed nonmedical personnel are not competent to treat patients psychologically and socially. Many psychiatrists treat their patients only with ECT or with prescription medication, a subject that has appeared in the pages of this journal many times.

Finally, I wonder why Dr. du Mas cited Freud's recommendation in favor of lay analysts—is he opposed to Freud's recommendation?

HANS A. ILLING, PH.D.
Inglewood, Calif.

Dr. du Mas Replies

SIR: Judging from correspondence and requests for reprints, my article is apparently being used as a teaching aid in both graduate and undergraduate courses. I wonder why such an "outdated, inaccurate, and . . . misleading" paper would be used in this way.

My generalizations about the nonmedical model are based on rational, and in some cases "mathematical," deductions. For example, a community mental health center (CMHC) I know of that operates under the nonmedical model had two full-time M.D.s, three Ph.D.s, and about 80 other personnel—a non-doctorate to doctorate ratio of 16 to 1. Service aides, therapists with B.S. degrees, etc., necessarily lower mean statistical parameters for group characteristics of nonmedical-model personnel in regard to training, IQ, clinical experience, etc. In medical-model institutions such as hospitals, doctors are the only people with final responsibility for all therapy.

Dr. Illing refers to the competency of "qualified and licensed" nonmedical people. How many personnel in the typical nonmedical-model CMHC satisfy these two criteria? I would estimate approximately 10 to 20 percent, which means that, according to Dr. Illing's own criteria, 80 to 90 percent are of questionable competence, even in psychosocial therapy.

It seems to me that Dr. Illing himself indirectly stated my own argument in his statements on the "whole person." He says that nonmedical people are qualified to treat the whole person psychologically and socially—not chemically, surgically, genetically, etc. This part of the whole person must be left to the physician.

I am not opposed to Freud's recommendation of lay analysts such as myself, provided they are sufficiently well trained to know their limitations and to place their patient's welfare first. There are few, if any, psychosocially derived symptoms that cannot be simulated by a single organic condition—organic brain syndrome. When nonmedical people treat a client without first ruling out organic, endocrinological, genetic, and other possibilities, our professional egos can literally jeopardize the lives of our clients. Therefore, M.D.s are more necessary to nonmedical mental health professionals than we are to them.

The truth hurts—unless we are willing to use it to improve our nonmedical intrusion into what has been a medical domain for centuries. Let's share our knowledge, work together, and learn from each other.

Augusta, Ga.

S. Weir Mitchell Rediscovered

SIR: In his paper, "Brief Therapy of Conversion Reactions: An In-Hospital Technique" (May 1974 issue), Richard A. Dickes, M.D., stated that he searched the recent literature and found no treatment approaches identical to the one he described. It is indeed true that the enormous volume of material produced, Xeroxed, and computerized these days makes it almost impossible for one to review recent as well as remote literature about anything.

Occasionally, literature from long ago can make a contribution. In 1875, S. Weir Mitchell (1) described a regime, primarily for the treatment of hysterics, that was similar to Dr. Dickes', although it was not identical. Thirty-three years later, Mitchell reported virtually a professional lifetime of experience with this treatment in an article entitled "The Treatment by Rest, Seclusion, etc., in Relation to Psychotherapy" (2). Although the "etc." included diet, massage, and electricity, Mitchell consistently put his primary emphasis on rest and seclusion.

Plus ça change, plus c'est la même chose.

C. KNIGHT ALDRICH, M.D.
Charlottesville, Va.

Dr. Dickes Replies

SIR: Dr. Aldrich has done me and the profession a service by highlighting S. Weir Mitchell's contributions. Mitchell's approach differed from the one described in my article in several ways, the principal similarity between them being the use of bed rest and isolation. We did not duplicate the prolonged time course of bed rest Mitchell used; in fact, our patients were encouraged to ambulate as rapidly as symptoms dissipated. Mitchell often avoided discontinuing bed rest if there was an initial loss of symptoms.

We used none of the special diets, massage, or special nurses Mitchell used. Our efforts were directed toward reinforcing adaptive behavior and permitting the development of some insight.

Mitchell's patients for the most part presented well-established, long-standing symptoms, while many of our patients had symptoms of more recent onset. We therefore had to consider preventing secondary gain from fixing the symptom in mental life. It was essential to keep the hospital setting from becoming more attractive than performance on duty. Prolonged bed rest would not have served this function and, as Mitchell was aware, lengthy bed rest has its own medical complications.

Bronx, N.Y.

Diagnosing Caffeinism

SIR: In the October 1974 issue of the *Journal*, John F. Greden, M.D., pointed out the importance of checking the caffeine intake of individuals who complain of anxiety symptoms, especially when these symptoms cannot be adequately explained by life circumstances and do not respond to ordinarily effective psychopharmacological agents ("Anxiety or Caffeinism: A Diagnostic Dilemma").

I recently saw an inmate at the Nevada State Prison who was complaining of severe anxiety symptoms that were unrelieved by high doses of minor tranquilizers or by other psychoactive agents. An inquiry about his intake of caffeine-containing substances revealed that he was consuming approximately 50 cups of coffee a day. He had a hot plate and a constant supply of coffee in his cell and, having little else to do with his time, he made and drank coffee constantly.

This patient originally expressed disbelief that his coffee intake could have anything to do with his symptoms. However, he did substitute decaffeinated coffee, cutting his total coffee consumption by 60 percent, and reported marked improvement in a very few days.

I would like to commend Dr. Greden for emphasizing the importance of this phenomenon and bringing it to the attention of clinicians.

DONALD A. MOLDE, M.D.
Reno, Nev.

Sybil: Grande Hystérie or Folie à Deux?

SIR: The proper diagnosis for multiple personality is grande hystérie, according to Dominick A. Barbara, M.D., in his review of *Sybil* (August 1974 issue). But the French have given us a still better diagnosis for this case—folie à deux. It is clear that the 16 selves said to be inhabiting Sybil's body were as real to her psychoanalyst as to Sybil herself. In fact, most of the time Sybil refused to accept their existence, while the analyst believed in their reality, even claiming to see and speak to them.

Thus one of the novelties in this case is that the analyst tried for years to persuade the patient to believe in a complex delusional system. One can only wonder how often this happens. Perhaps the publication of *Sybil* will encourage others to reveal their unconventional therapeutic techniques. This possibility lends support to Dr. Barbara's suggestion that *Sybil* "is destined to stand as a significant landmark in psychiatry and literature."

We know that psychiatry as popular literature often resembles a fairy tale, and *Sybil* is no exception. Even though the book seems to be intended for a youthful audience, serious inferences may nonetheless be drawn from it.

I would suggest that the likelihood of a diagnosis of multiple personality (or grande hystérie) being made is positively correlated with the romantic and fanciful tendencies of the diagnostician.

It is a kindness that Freud did not live to see Sybil's fairy godmother identified in a scholarly psychiatric journal as a psychoanalyst engaged in psychoanalysis of an "essentially Freudian" orientation.

GEORGE VICTOR, PH.D.
Livingston, N.J.

Dr. Barbara Replies

SIR: Dr. Victor's letter is a distortion of fact. He should know that multiple personality, an established medical entity, is not a "complex delusional system" or a delusion at all on the part of either the therapist or patient. The alternating selves provide a system of dissociation whereby the waking self is defended against intolerable and therefore buried emotions. Sybil was amnesic for parts of herself—the alternations—because they carried the burden of the memories she had repressed and denied. The alternating selves are thus the objectification and acting out of repressed materials, the usual arsenal of psychoanalysis. To say that "most of the time Sybil refused to accept their [the alternating selves'] existence, while the analyst believed in their reality—even claiming to see and speak to them" is to misunderstand the dynamics of the case. Sybil refused to accept the existence of the memories she denied and therefore, by definition, the unconscious caretakers of those memories. On the other hand, Dr. Cornelia B. Wilbur, the analyst, could talk to these alternations not because she had deluded herself into being able to do so, but because "they" were parts of her patient. She not only talked to them but sometimes recorded what they said. There is nothing fanciful, mystical, or delusory about the "they," who represented dissociated parts of a real person.

These parts, however, were differentiated by self-image, by the way they functioned, and by their speech. Flora Rheta Schreiber, the author of *Sybil*, is a professor of speech at the City University of New York's John Jay College of Criminal Justice. Listening to the tape recordings of Sybil's alternations as part of her herculean research, Prof. Schreiber noted differences in the alternations in diction and accent, as well as in vocabulary, grammar, and intonation. Why, since the selves are part of Sybil, do they speak with different voices? The answer is that the selves, on certain levels, were identifications with people in Sybil's life, and their voices coincided with the person with whom the identification was made.

Contrary to what Dr. Victor says, it is too bad that Freud is not alive to read *Sybil*, which epitomizes some of his deepest

convictions. The unconventional psychoanalytic techniques of Sybil's therapist are reminiscent of those he himself employed in his patients' analyses. In fact, Prof. Schreiber quotes Freud as follows:

> The whole multiplicity of the problems of consciousness can only be grasped by an analysis of the thought-processes in hysteria .... Examples of every possible variety of how a thought can be withheld from consciousness or force its way into consciousness under certain limitations are to be found included within the framework of psycho-neurotic phenomena.

She then adds, "If you translate 'thoughts' into 'secondary selves,' you have the analog [of the case of Sybil]" (p. 349). In conclusion, far from dealing with the fanciful, *Sybil* works within the framework of established Freudian concepts.

Lawrence, N.Y.

In Appreciation of the "New Chairman"

SIR: This is a heartfelt word of appreciation for Dr. Arnold Mandell's witty and penetrating analysis of the recent history of psychiatric education, particularly of the radically altered role of the departmental chairman ("The Changing Face of Chairmen of Psychiatry Departments in America: An Opinion," October 1974 issue).

As one of the many academic psychiatrists who have consistently declined chairmanship offers—and for the very reasons so incisively stated by Dr. Mandell—I heartily concur that today's chairman is and should be a different breed of cat.

Chairmanship search committees would be well advised to seek candidates with demonstrated managerial talent and political adeptness. I quite agree that there is little reason to expect the return of the charismatic, life-tenured "grand old man" chairman of the pre-1950s era. However, I cannot help but wonder if a great share of the teaching responsibility in psychiatry will not soon be recovered by a cadre of biologically and medically oriented, eclectic, experienced, and humanistic "grand old men" (or, at least, "good old guys").

If this happens, they will certainly need all the support and protection they can get from Dr. Mandell's "new chairman." This person may not be celebrated for his contribution to the literature or his teaching or clinical abilities, but those of us who are privileged to work under the direction of someone with the managerial virtues described by Dr. Mandell can approve and appreciate the talents he does have rather than vilifying him for those he does not. It is to be hoped that we will soon stop looking upon the chairman as a necessary evil, regarding him instead as a truly necessary and welcome person.

DONALD J. HOLMES
Carefree, Ariz.

Credit Where Credit Is Due

SIR: I read Dr. Stanley Greenspan's article "The Clinical Use of Operant Learning Approaches: Some Complex Issues" (August 1974 issue) with enthusiasm. He concisely phrased observations about behavior therapy that I have labored to clarify. However, I was startled that he did not recommend help from psychoanalytic knowledge to accomplish the necessary task of "understand[ing] the entire behavior pattern of an individual." His language is, with one exception, devoid of psychodynamic terms. The general concepts and problems he outlined have long been known and understood by psychoanalytic and psychodynamic psychotherapists, and many of his points are restatements of their knowledge.

In asserting that the question of what should be treated involves both the therapist's input and the patient's choice of the areas he wants to work on, Dr. Greenspan noted that this mutual choice is made from a position of understanding the patient's total personality. This requires sufficient nondirective therapy to allow continuous reevaluation of goals; psychoanalysts might call this "listening with the third ear." Dr. Greenspan's structuring of a series of small, gradual steps involving changing goals that lead to desired results might be spoken of as working through successive layers of resistance and/or maturational phases. Being locked into a particular behavior because of prematurely rigid goals resulting in a compromise of the patient's attainment of true autonomy may be thought of as an impasse in treatment caused by countertransference.

Such comparisons transposing clinical or theoretical material from behavior principles to psychodynamic principles and back is easy to do and has become a frequent exercise for students. My point is simply that justice should be done to one's trailblazers.

However, Dr. Greenspan undoubtedly used good judgment in not including such comparisons in his article, as doing so would have encumbered and perhaps detracted from his thesis and might have irritated some of his readers. Nevertheless, I would like to acknowledge the psychodynamic formulations of the clinical observations Dr. Greenspan describes in behavioral language.

R.W. BURGOYNE, M.D.
Los Angeles, Calif.

Dr. Greenspan Replies

SIR: I would like to thank Dr. Burgoyne for his perceptive and sensitive comments. As he suggests, my discussion of operant learning techniques derives in part from an understanding of personality organization stimulated by psychoanalytic concepts and methods of exploration. He is also correct in assuming that I avoided explicitly stating the psychodynamic contributions and points of comparison in the interest not only of clarity and conciseness but of communication with mental health professionals who do not use psychodynamic formulations.

Most importantly, I tried to demonstrate the complexity of behavioral phenomena in strictly behavioral language to avoid the dichotomies stimulated by theoretical comparisons and to show that an understanding of the intricacies of behavior is essential, regardless of one's orientation in theory or practice.

I have, however, attempted to deal with the theoretical and practical comparison and integration of behavioral learning and psychoanalytic models and techniques in other works (1–3).

I would like to thank Dr. Burgoyne again for his helpful comments.

A Perceptive Patient

SIR: I was recently reminded of something we were all taught as residents—the need to choose our words carefully when speaking in front of catatonic patients, who are far more aware of their surroundings than their outward appearance suggests. On my daily visit to a physically ill, very deaf, and almost blind 74-year-old catatonic patient, I waved my hand and put on a broad smile as I approached. I then leaned close and shouted my "good morning." She broke her usual silence with the only sentence of her day: "You have been eating onions."

WILLIAM L. CLOVIS, M.D.
Philadelphia, Pa.

On the Rationale and Consequences of the "Illness" Label

SIR: While reading Seymour Kety's "From Rationalization to Reason" (September 1974 issue), I was reminded of the standard response of any bureaucrat when he is challenged on why he is performing a particular function: "I don't make the rules, I only follow them." Dr. Kety follows the rules of scientific methodology scrupulously, but apparently he has chosen to ignore the implications of his research and commentary.

There may well be a set of behavioral responses determined by genetic as well as environmental and psychological factors that can be accurately recognized and labeled as the "illness" of schizophrenia, but any personality trait, attitude, cognitive style, etc., may have genetic components, just as there may be a genetic predisposition to diabetes. However, this begs the question: What should be done about this set of responses? Dr. Kety goes along with the rules, and labels the set an "illness." Well, homosexuality was an illness yesterday; what is it today? Marijuana use is a symptom of an "illness" today; was this the case before the Marijuana Act of 1937? And what will society call it after it has been decriminalized?

Neither rationalization nor reason will change current societal attitudes toward illness. While society's response to one who is "ill" may range from revulsion and fear to pity and compassion, all of these responses imply some form of avoidance or distance. As Dr. Kety repeatedly emphasized, illness is to be prevented, conquered, treated, and eliminated, but the implication is that it is never to be tolerated. Is this a therapeutic attitude toward schizophrenic patients?

The comparison of schizophrenia with diabetes is a weak tactic to avoid the implications of illness labeling. Not only are the sequelae of untreated diabetes entirely organic in origin, but they are unaffected by societal attitudes toward diabetes. Insulin, not society, determines the course of diabetes. Can the same be even intimated for schizophrenia?

It should be noted that Dr. Kety's conclusions are cautious and well founded. But what would the information that there is a clearly demonstrable genetic predisposition to schizophrenia lead society to do? He implies that this question will not be asked or, if asked, that it should be answered by someone other than psychiatrists. After all, he tells us that "psychiatry is in an identity crisis precisely because it has branched out beyond mental illness into problems it is not especially qualified to handle. . . ." I submit that if we do not anticipate these questions and attempt to answer them within a frame of reference consistent with our profession, we are not only evading responsibility for the knowledge that we generate, we are leaving the answers to be formulated by members of other professions, such as politicians or policemen.

Computers, questionnaires, and kappa values may exist in a social vacuum, but my patients do not. While I applaud the excellent research conducted by Dr. Kety and others attempting to explain schizophrenia, I believe that focusing solely on "the salutary consequences that are an inherent part of the medical model . . ." and denying or ignoring the consequences for the individual when schizophrenia is labeled an illness is to perpetuate psychiatry's "identity crisis" with rationalization rather than with reason.

THOMAS J. KAISER, M.D.
Camarillo, Calif.

Misspellings and the Potential for Violence

SIR: I wish to comment on Dr. Bernard L. Diamond's review of my book, *The Murdering Mind* (September 1974 issue). Dr. Diamond is quoting me out of context when he mentions that I list habitual misspellings as probably relating to a potential for violence. Misspelling in and by itself is not a sign of potential violence. What I have said is that this sign in conjunction with others may be an indication that an individual may later become violent. I have also mentioned, as Dr. Diamond states, that the signs listed may also indicate emotional disturbances that do not necessarily result in murder. As I stated in *The Murdering Mind*:

> The spelling errors are measurable symptoms which can, if confirmed in large-scale research data, be used as a means of detecting the potentially violent or murderous person. Where in addition we find habitual truancy and other early symptoms, as mentioned before, we must be on the alert for latent violence. (p. 28)

A more serious problem is that Dr. Diamond did not mention the main thesis of my book, the intimate connection so often found between murderer and victim—the concept of victimology—"a link . . . which is most often overlooked or simply omitted when a case comes to trial." This oversight is most regrettable.

DAVID ABRAHAMSEN, M.D.
New York, N.Y.

Messages of the Body, *by John Spiegel and Pavel Machotka. New York, N.Y., Free Press (Macmillan Publishing Co.), 1974, 426 pp., $17.95.*

This well-written book presents a method for studying how body movements, gestures, and postures function in human communication. It also reports on some experiments designed to show the effectiveness of this method.

In the first three chapters, Dr. Spiegel reviews the literature on the function of body movements in human communication. One chapter is devoted to dance and another to mime. In the fourth chapter, he presents an excellent summary of the various scientific research strategies that have been used to study nonverbal communication. He specifically criticizes the idea that body communication functions in an analagous way to verbal communication.

Dr. Spiegel presents his system for organizing and categorizing body movements, which he terms "presenting behaviors," and defines as consciously or unconsciously intentional arrangements of stimuli emitted in the presence of another person to evoke a desired response. He stresses the point that, although presenting behaviors function as observable links between internal processes and external situations, they can be studied independently of both the inner state of the organism and its external situation.

In the following chapters, Dr. Spiegel develops hypothetical categories for organizing and describing presenting behaviors as they occur consecutively through time.

The concept of presenting behaviors is central to the book's method for studying nonverbal behavior. Linguists have called what Dr. Spiegel calls a presenting behavior an element in the structure of expression (1). This concept has been an important part of the linguistic method.

In chapters 9 through 16, Dr. Machotka presents the results of some experiments designed to test the usefulness of Dr. Spiegel's hypothetical categories for organizing body presentations. Dr. Machotka studied how line drawings of certain body behaviors were interpreted by a series of subjects. These subjects were asked to compare the meanings of drawings of human figures in systematically varying body presentations along several measurements using Osgood's Semantic Differential Scale.

The data indicate the meaning the subjects attached to each specific alteration in body presentation. This method was used to study such presentations as genital-covering versus genital-exposing arm and hand positions, clothing versus nudity, and the effect of the direction of gaze on dominance within a group of people.

In chapter 17, Paul Williams reverses the method used by Dr. Machotka. He asks subjects to position flexible wooden manikins to create body configurations that would communicate the specific idea or affect found by the subjects in Machotka's experiment.

I have two major criticisms of this book's method for studying nonverbal communication. First, the categories used to organize and describe presenting behaviors were selected a priori on the basis of theoretical assumptions. Second, the presenting behaviors themselves were arbitrarily selected from classical paintings.

The book shows, however, that statistically reliable data can be compiled by the method described by Dr. Spiegel. The data themselves provide a useful estimate of the meanings of the roughly defined presenting behaviors. This book is a welcome addition to the literature on nonverbal communication.

FELIX F. LOEB, JR., M.D.
La Jolla, Calif.

About Behaviorism, *by B.F. Skinner. New York, N.Y., Alfred A. Knopf, 1974, 256 pp., $6.95.*

In the introduction to this volume, B.F. Skinner refuses to accept the mantle of *the* behaviorist that was worn by John B. Watson in the early part of this century. Despite this disclaimer, it appears to me that this mantle has been popularly bestowed upon Skinner and, like Watson, he is reaping its benefits, both positive and negative.

It is very stylish to be either for or against B.F. Skinner and whatever it is that he represents. In order to broadly conceptualize an entire body of information on contingencies of reinforcement, it is probably easier to subsume it under a single name, thus placing Skinner alongside Darwin, Newton, Freud, and many others who have been chosen to represent a particular thrust in science or philosophy. What is often lost in this global generalization is the actual contribution and thoughts of the man. Instead one sees a conglomerate of widely varying contributions, often by many of lesser talent, that are attributed to the man himself.

In most instances, comments concerning a "Skinnerian" view of human behavior do not reflect Skinner's work or thoughts but those of many investigators who use some of his ideas to approach a diversity of human problems. Nowhere is this clearer than in Skinner's concern about the use of aversive stimulation, the influence of a deprived environment on social behavior, and the use of behavioral strategies on captive populations. His approach to these phenomena is inferred from the application by others of behavioral principles to self-destructive children, prison populations, juvenile detention facilities, and the retarded, but they are not derived from Skinner's actual behavior. Skinner's being called fascist, antidemocratic, a pseudoscientist, and a dehumanizer is based on presuppositions that bear little relationship to his experimental work and extrapolations to human behavior and its vicissitudes. Thus it is important that *About Behaviorism* is written by Skinner himself to correct some misapprehensions about what he represents and what contributions radical behaviorism can make to the understanding of human behavior.

The essence of this volume is an explication of 20 commonly held assumptions about behaviorism, including such diverse notions as that it ignores consciousness and feeling states, that it is dehumanizing, antidemocratic, and scientistic, and that it reduces man to an automaton, neglects innate endowment, and does not account for cognitive processes. Although Skinner takes issue with many who represent these positions, he does

not disregard their findings. Rather, he suggests that the data can be examined from a much more economical perspective by examining actual behavior in the context of contingencies of survival and reinforcement rather than through the perspectives of "humanism," "mentalism," and various forms of "structuralism." His arguments are compelling as he lays about in all directions to unhorse a group of authors whom he does not mention by name but about whom he states,

> I express my regrets if the authors would have preferred to be given credit, but I have applied the Golden Rule and have done unto others what I should have wished to have done [to me] if I had used such expressions.

It does not take a great deal of imagination to recognize whom he is criticizing for using a mentalistic or structuralistic approach to human behavior when he discusses innate language mechanisms (Chomsky), ego, id, and superego conflicts (Freud), developmental unfolding (Piaget), and stages in the life of man (Erikson), to name a few. Nevertheless, his arguments are soundly reasoned and provide an extremely interesting view of human behavior, although the terms used to describe it do not carry the impact of the pathetic fallacy in literature or the commonly used phrases that endow man with a mental life glowingly called a thing of wonder and beyond all comprehension. As Skinner points out, this latter view stops all investigation of behavior and closes a neat tautological ring.

One prerequisite for reading this book is some knowledge of the strategies and definitions of reinforcement learning. Another is an open mind to more parsimonious explanations of human behavior. There are some areas where one could take issue with Prof. Skinner. Despite his denials, he studiously avoids the "between-the-skin" space of the human being. He thus runs the risk of being unable to account for certain human peculiarities that in medicine are more obvious through their pathology than through their usual characteristics. Here I refer to the peculiarities of schizophrenia, manic-depressive disease, organic brain syndromes, childhood psychosis, and aphasia, where the usual operating contingencies of survival and reinforcement are uniquely distorted by what exists between the skin.

Despite this reservation, I am strongly compelled by Skinner's arguments. It appears to me that his approach to understanding human behavior will probably assume greater significance in the long run. For those who have an open mind concerning B.F. Skinner, this book should clearly show him as the consistently behaving philosopher of science who nonetheless is an obvious romantic who can enjoy being human without having to explain it beyond his data.

Mental Health Care in the World of Work, *by Hyman J. Weiner, Sheila H. Akabas, and John J. Sommer. New York, N.Y., Association Press, 1973, 182 pp., $8.95.*

Since the literature on mental health research in a work setting is sparse, the project described in this book is of special interest. Funded by the U.S. Department of Health, Education, and Welfare, the project involved workers in the men's clothing industry in New York City. Its primary focus was to offer mental health services to persons who found that emotional illness was hindering their job performance; the goal was to maintain them on the job, or, if they had stopped working, to return them to the job.

The authors do not suggest a cause-effect relationship between the work setting and mental illness. Rather, they see the work environment as relatively neutral, even though many of the jobs in the men's clothing industry are mechanical and repetitive and there is a great deal of pressure to produce (most employees are paid on a piecework basis).

One of the important findings of the research is that many mentally ill persons can continue working. "We were constantly amazed," the authors observe, "by the way in which women and men with severe emotional disorders were able to function on the job" (p. 156). Noting that psychiatric case histories from other settings are replete with examples of workers who fell by the wayside, they suggest that "modest efforts at intervention could influence this tide" (p. 156).

As far as actual treatment was concerned, the researchers found that in psychotherapy these blue-collar workers were usually verbal and expressive, were able to develop a capacity for self-awareness, and often rejected psychotropic drugs as potentially habit forming. The authors had the impression (shared by those who have treated blue-collar workers in other settings) that the active, directive therapist is somewhat more successful than the one who adopts a relatively passive therapeutic posture.

The authors observe that ours is one of the few industrialized countries lacking a work-rehabilitation philosophy; the present system is one in which a vocational counselor usually places an individual on a job *after* his treatment program is completed. They advocate a view that "sees the world of work as the context and partner in the rehabilitation process" (p. 156).

Not all of the experience gained in this project can be generalized to other work settings. Both the men's clothing industry, with its many small manufacturers, and the Amalgamated Clothing Workers union, whose representatives assisted in involving the mentally ill workers in treatment, have some characteristics that make the situation described by these authors unique. But this book will be useful to all those treating blue-collar workers and also to those involved in setting up comprehensive mental health programs in many kinds of settings.

Benzodiazepines in Clinical Practice, *by David J. Greenblatt, M.D., and Richard I. Shader, M.D. New York, N.Y., Raven Press, 1974, 293 pp., $14.50.*

Since they became clinically available in 1960, the benzodiazepines have emerged as the most frequently prescribed psychopharmacological agents for the distressing symptoms of anxiety. During one year's time, at least 1 in 10 Americans takes a benzodiazepine tranquilizer or hypnotic. There is therefore an obvious need for a concise review of the voluminous literature on these agents—ranging from their pharmacological properties to their clinical indications and usefulness.

Drs. Greenblatt and Shader have splendidly distilled the literature on benzodiazepines into a succinct volume that provides an excellent rational therapeutic guide for the practicing psychiatrist. They have reviewed the entire English literature on the benzodiazepines; 2,000 references are critically reviewed and incorporated into this volume. Yet this is not a ponderous reference work that focuses on minute details. It addresses itself directly to clinical therapeutics.

The book consists of 13 sections, 6 special appendices, and an index. Three sections provide a concise review of the biochemical, neurophysiological, neuropharmacological, and behavioral

pharmacology of the benzodiazepines. The authors cite what is known and what is conjectural at this time.

The remaining sections—the bulk of the book—focus on treatment, indications, and experiences. The roles of the benzodiazepines in emotional disorders, neuromuscular and seizure disorders, sleep disturbances, alcoholism and other drug-dependent disorders, and surgical procedures (i.e., anesthesia) are sequentially reviewed.

The authors also review the effects of the benzodiazepines on organ systems and their relationships to experimental stress and performance. These two sections splendidly combine the applied psychopharmacological aspects of these agents to the body as a whole. They deal with effects of the drug on the different organ systems and on their allied performance boundaries. In uncluttered terms, the book notes that the benzodiazepines have few effects beyond the central nervous system. Accordingly, they can be used in the psychophysiological disorders to alter the target symptoms of anxiety without interfering with the status of the major organ systems—truly a blessing in the terribly complex management of so-called psychosomatic disorders.

The section on stress pinpoints the noted physiological dysfunctions (i.e., reaction time, coordination) of specific bodily reactions to the drug. Side effects are reviewed thoroughly; both tentative and firm guidelines are provided. There is a large abuse potential with the benzodiazepines, and the authors clearly document and underscore this dimension. This particular section is a model of all the sections of this book: the material is presented in a clear, concise, and unbiased fashion replete with a concluding summary that synthesizes the essentials of this aspect of the benzodiazepines.

This is a superb book, one that I believe will become a model for future reviews of the clinical "state of the art" of specific psychopharmacological agents. The two authors have brought together a ready resource guide for the psychiatric practitioner, family physician, and trainee. It should be read by all colleagues who pride themselves in keeping abreast of the major treatment approaches in modern psychiatry.

Omaha, Neb.

Mental Health Programs for Preschool Children: A Field Study, *by Raymond M. Glasscote, M.A., and Michael E. Fishman, M.D. Washington, D.C., Joint Information Service of the American Psychiatric Association and the National Association for Mental Health, 1974, 182 pp., $7.00.*

This is an extremely important book for people concerned about young children and the programs available to them when they are in need. If it is true that 1 out of 10 children will be considered emotionally impaired sometime during their childhood, then such programs are not a luxury but a necessity.

This descriptive study of seven mental health programs for preschool children, the twelfth in a series by the Joint Information Service of the American Psychiatric Association and the National Association of Mental Health, is an extension of a study of children served in community mental health centers (1). It was found in the previous study that only 2 percent of the children served by eight community mental health centers were of preschool age. This current study was undertaken to raise the level of awareness of needs for this age group. It eminently succeeds in this endeavor.

The book is divided into two parts. The first is a summary of more than 300 articles dealing with emotionally disturbed young children and the emotional needs and development of all young children. Some of the works of Piaget, Provence, Eisenberg, Erikson, Rabin, Roberts, Rowley, Fraiberg, Kanner, Anthony, and many others are condensed and organized by topic. Areas covered include principles, needs, the mother, beyond home and mother, and emotionally disturbed children. The section is brief, concise, and well written. It provides the background and principles for the major part of the book, which details the programs themselves.

Included in part 2 of the book are detailed descriptions of the Dubnoff Center for Child Development in North Hollywood, four interrelated programs in Topeka, Project Enlightenment in Raleigh, the Development Center for Autistic Children in Philadelphia, the Martin Luther King, Jr., Parent-Child Center in Baltimore, the Division of Child Psychiatry of Cedars-Sinai Medical Center in Los Angeles, and the Preschool Unit of the Cambridge-Somerville Mental Health and Retardation Center in Massachusetts. These centers were selected on the advice of "reliable people" and represent different goals, orientations, and philosophies. Each center is discussed in terms of its history, eligibility, geographic area served, philosophy, rationale, system employed, and administrative functioning. The latter includes a discussion of such areas as funding and record keeping, staff, physical plant, program, evaluation, and aspirations.

After reading these descriptions, one feels intimately familiar with each center—its achievements, concern for children, creative and resourceful use of facilities and manpower, and frustrations. What becomes very clear is the need for follow-up and outcome studies to evaluate what is being done or not being done and the complex, often inadequate funding available to such centers. The demand of funding agencies to know results before they will fund programs, even though such programs seem right and are administered by competent, compassionate people, precludes a ready source of money. Added to this, of course, is the low priority our country generally gives to preschool children.

Most of the centers described are in a dilemma. They have barely enough funds to maintain their standards of care, let alone do outcome studies, which are becoming increasingly necessary for further funding. Few programs across the country have the luxury of built-in funds for longitudinal follow-up and outcome measures. At least one exception, fortunately, is the Brookline Early Education Project (2), which, however, deals with a general population of preschool children in terms of early educational intervention and identifying children at risk. This center follows children from birth to second grade. The study is done on a careful cost-accounting basis and outcome is a major part of the work. Such studies are needed for children identified as emotionally disturbed or at risk.

If we assume that psychological intervention makes a difference and that the earlier the intervention the more favorable the outcome, priority must be given to these young children. Comprehensive services for the preschool child and evaluation of such services must be funded and provided. Humanity demands it; science demands it.

The International Pilot Study of Schizophrenia, vol. 1, *by the World Health Organization. Geneva, Switzerland, WHO, 1973, 412 pp., 56 Swiss francs (paper).*

The origins of this massive transcultural study date back to 1959, when the World Health Organization (WHO) convened an expert committee on the epidemiology of mental disorders. This committee stressed the need for reliable and valid data on the incidence and prevalence of mental disorders and recommended WHO assistance in the international coordination of studies aimed at solving problems of observation, classification, recording, counting, and research design.

Later publications and meetings led to a meeting of a WHO scientific group in 1964 that recommended the development of methods necessary to carry out transcultural research in psychiatric epidemiology. In subsequent years the initial plan for the International Pilot Study of Schizophrenia (IPSS) was worked out and funds were made available by the U.S. National Institute of Mental Health (NIMH) as well as by WHO and the collaborating field research centers.

The IPSS is part of WHO's long-term plan in psychiatric epidemiology and social psychiatry designed to implement the recommendations of the scientific group. This plan has four interlinked programs. Program A is concerned with the standardization of psychiatric diagnosis, classification, and statistics. Program B is intended to determine whether comparable cases of mental disorder can be identified in various populations throughout the world. Program C was seen as developing out of Program A and B and will consist of comprehensive epidemiological studies of specific mental illnesses in defined populations. Program D, also planned as a development of the earlier programs, will be an international research training program in psychiatric epidemiology and social psychiatry.

The aims of the IPSS, the major vehicle of Program B, were to seek answers to such basic questions as the following:

1. In what sense can it be said that schizophrenic disorders exist in different parts of the world? Do they differ in form or content? Does the clinical course differ?
2. Can other functional psychoses also be recognized? Do they run a recognizably different course?
3. Can techniques be developed for recording and classifying symptomatology reliably?
4. Can teams of research workers be trained to use these techniques so that comparable observations can be made in both developed and developing countries?

The design was that of a prospective follow-up study, with cases selected by a series of screening procedures and examined with standard instruments in nine field research centers located in different parts of the world. A modified version of Wing's Present State Examination (1) was the major psychiatric rating measure. This was carefully translated into the eight languages used by the collaborating investigators. Over 1,200 patients were included in the study, and approximately 1,600 items of information were obtained for each patient. Thus about 2,000,000 items of information had to be condensed into comprehensible proportions by a complex set of procedures.

This volume details practical information on the management and operation of the project from its inception. There are chapters describing the instruments; the problems of translating psychiatric terms into languages as diverse as Chinese, Czech, Danish, Hindi, Russian, Spanish, and Yoruba; the methods of statistical analysis; the characteristics of the patients; and several methods of classification, including cluster analysis and clinical classification by computer.

The results of the study show that the procedures chosen were adequate to find schizophrenia, manic and depressive psychoses, and neuroses in the nine field research centers. The study also shows that the techniques used permit studies of schizophrenia to be carried out in different parts of the world with the assurance that results will be comparable. It was evident that similar groups of schizophrenics could be found in each of the nine centers, that valid and reliable research instruments could be developed for practical use in international psychiatric studies, and that teams of psychiatrists and other mental health workers from different theoretical backgrounds and widely separated cultures and socioeconomic conditions could collaborate in a large-scale international study.

This report presents the results of the detailed initial evaluation phase only; follow-up evaluations at one and two years will appear in the future. The reader will be impressed by the scale of the study, the years of planning needed to ensure its success, the sheer volume of the data, and the intricate methods of statistical analysis. The international network of centers in countries at various stages of development can serve as a basis for future research and training in psychiatric epidemiology. It is to be hoped that funding will be available to continue research at these centers.

This volume is reproduced by photo-offset from typescript and paperbound in an unsewn binding. This has the advantage of inexpensive and rapid production but the disadvantage of impermanence; the pages cannot be expected to remain in the binding after one thorough reading, and library shelf life is likely to be short. If subsequent reports are to be similarly produced, the collaborating investigators should be encouraged to prepare a hardbound volume to ensure the survival in print of this milestone of research in psychiatric epidemiology and social psychiatry.

Belle Mead, N.J.

Changing Human Behavior: Principles of Planned Intervention, *by Ralph K. Schwitzgebel and David A. Kolb. New York, N.Y., McGraw-Hill Book Co., 1973, 318 pp., $10.50.*

The main thrust of this book is the concern of the authors about the spiraling quantity of work being done with regard to human behavioral change, the lack of established basic guidelines, and the need to upgrade the overall quality of this output. The authors claim to espouse no particular therapeutic approach but, rather, to formulate basic principles for planned intervention into human systems.

They formulate the following principles: 1) intervention in human systems should be based on scientifically verified principles of behavioral change; 2) the behavior should be empirically defined and observed over a reasonable length of time; 3) procedures should be explained in ways that can be replicated by others; and 4) application of behavioral change should be directed toward meaningful and personally significant human behaviors as opposed to contrived laboratory situations.

The book itself is divided into two basic parts. The first deals with specific theoretical approaches, their historical evolution, and suggested areas for further investigation. While many of these techniques are associated with "behavioral modification," the authors' use of the terminology is oriented toward research.

The second section of the book deals with such research-oriented considerations as observation and recording of behavior, assessment of change, and ethics associated with human experimentation and manipulation.

The authors are to be commended for their efforts to present a measured appraisal of the field of behavioral change. The book is knowledgeable, well referenced, well organized, and readable. While the first half of the book would appeal more to the neophyte, the second half is more interesting to the trained behavioral scientist because it clearly delineates the pitfalls of human research and injects a note of humanity and human dignity.

With the increasing encroachment of third-party-payment organizations into the physician-patient relationship, demonstrable efficacy of treatment will be of vital importance in the future. This book raises important questions about the present state of the behavioral sciences and provides valuable guidance for continued refinements of research techniques geared toward achieving a more meaningful body of knowledge. While this book would have limited appeal for the full-time clinician, it should be required reading for anyone dealing in behavior change research.

MAJ. THOMAS C. BOND, MC, USA
Ft. Leavenworth, Kans.

The Lesbian Myth, *by Bettie Wysor. New York, N.Y., Random House, 1974, 428 pp., $8.95.*

This book should be of interest to many members of APA in light of the recent ruling by the APA Board of Trustees that homosexuality "by itself does not necessarily constitute a psychiatric disorder" and that changed the listing of homosexuality in the *Diagnostic and Statistical Manual of Mental Disorders* (second edition) to "sexual orientation disturbance." Ms. Wysor's theses, as stated in the introduction, are as follows:

> My research into the subject [lesbianism] had convinced me that there is actually no such thing as heterosexuality or homosexuality; there is only *sexuality*, upon which has been imposed a social and moral structure which demands sharply defined sex roles and ritual sexual behavior. . . .
>
> Only when people of varying life styles feel free to come into the open—where they can exhibit their humanness, their worth and their usefulness to society—can people get to know them, stop mis-imagining, and realize that they can accept people who chose a different way of life without any threat to themselves or society. (pp. xi, xii, xvi)

The book is divided into two parts. Part 1 deals with "The Scholars: Theology, Science, Literature" and part 2 deals with "The People: Discussions Among Lesbians."

Part 1 is thought provoking and interesting, especially its first four chapters. The author has obviously devoted a good deal of time to careful research on the biblical sources of many contemporary ideas and attitudes. These chapters and the bibliographic documentation held the most interest for me. The remaining two chapters, on "Psychiatry, Homosexuality and Bisexuality" and "Lesbianism in Literature," are more pervaded by Ms. Wysor's particular point of view.

Part 2 consists of four tape-recorded discussion groups, one of which was a therapy group. Approximately 30 different women who have fully or partially adopted the lesbian lifestyle took part in these discussions. The chapter titles in this section are often misleading in that they represent the topic on which the leader had hoped to focus. All of the women lived in the area of New York City and most seemed to be of upper-middle-class background. This lack of heterogeneity left me with many doubts about the representativeness of their experience and views.

Undoubtedly, as we move into the last quarter of this century psychiatrists will encounter many more patients who are openly bisexual and homosexual in their personal practices. Ms. Wysor's book may provide a starting place for those who wish to consider such patients and their sometimes deeply troubling problems. It also offers us a chance to hear first-hand the thoughts of some lesbian and bisexual women who do not see themselves in the role of patient.

NANCY A. DURANT, M.D.
Plainfield, N.J.

From Diagnosis to Treatment: An Approach to Treatment Planning for the Emotionally Disturbed Child. Report 87, *by the Committee on Child Psychiatry, Group for the Advancement of Psychiatry. New York, N.Y., GAP, 1973, 146 pp., $4.00 (paper).*

This volume on treatment planning is one of a series of reports formulated by the Committee on Child Psychiatry of the Group for the Advancement of Psychiatry. A broad view of treatment is taken by the committee, the term being used to encompass "an extended range of curative, ameliorative, and health-promoting procedures." Treatment planning is defined as "the process which takes place between the diagnostic formulation and the ultimate treatment recommendations."

The principles of differential treatment planning, the assessment of therapeutic potential, and the communication of diagnostic findings and therapeutic recommendations are discussed clearly and concisely. Of particular value, in my opinion, is the stress laid on the role of the community. The need to assess the therapeutic potential in the child's community, the need to accurately communicate diagnostic findings and therapeutic recommendations to the referring source in the community, and the need for a working knowledge of community resources are all properly emphasized. A model of how to attain this latter knowledge is presented by the Ginsburg Fellow on the committee in a personal account of his efforts to ascertain the assets of his community on first entering practice as the only child psychiatrist in a midwestern state.

The chapter presenting different treatment plans formulated for the same cases by consultants from markedly different clinical settings makes for stimulating and worthwhile reading, as does the chapter outlining 14 common stereotypes and misconceptions about the psychiatric treatment of children. However, it appears to me that some of these stereotypes may be actually maintained in some sections of this report.

For example, one stereotype listed is "Rapid symptom removal is bad." Yet symptom removal is not mentioned as one of the goals of therapeutic intervention (p. 604), and it is stated that on occasion symptom removal "does not allow us to get at the cause of the symptom, and the cause will then find another outlet." Evidence in the literature for such symptom substitution is lacking.

"The only good therapy is psychotherapy" is another stereotype listed. However, a good deal of what is discussed in the volume would appear to apply primarily to dynamically oriented psychotherapy. Statements like the following would seem to indicate that emotional problems of children can be conceptualized only in a dynamic framework: "Families deserve the pre-

sentation of a dynamic formulation . . ." (p. 591); "The routine use of psychodynamic formulation . . . [is] a guide to optimal intervention" (p. 566).

Finally, the point is well made that follow-up studies of untreated children and children treated by different methods are lacking. Thus the treatment modality selected in most cases depends more on the subjective bias of the clinician than on hard evidence that the modality selected is the most effective for a particular emotional problem. This being so, it would seem that more stress should have been placed in this report on the need to systematically evaluate the effectiveness of treatment plans so that the data we sorely lack now will be available for future clinicians.

Overall, this report will make worthwhile reading for professionals of all disciplines involved in the care of emotionally disturbed children and their families.

DENNIS P. CANTWELL, M.D.
Los Angeles, Calif.

The Measurement of Intelligence, *by H.J. Eysenck, Ph.D., D.Sc. Baltimore, Md., Williams & Wilkins Co., 1973, 488 pp., $19.00.*

In these days when so much emotion is generated by any discussion of intelligence, it is reassuring as a scientist to read a book whose author claims in the foreword that the main justification for the book is the belief that "facts are essential in coming to reasonable judgments."

Dr. Eysenck's concern in this volume is with the facts generated by the measurement of intelligence, not with their social, ethical, or political implications. These he puts aside for another day. He states that intelligence is not a thing but a concept, a working hypothesis, a model, or a paradigm. Its meaning is derived from the structure and coherence of the data resulting from its measurement. The question posed here is a simple one: Has the working concept of intelligence generated through its measurement any significant body of reliable, valid data to justify its use? The social, economic, ethical, and political value of these data is a matter for later consideration.

To get his answer Eysenck surveys the work on the measurement of intelligence over the last 50 years. He presents his survey by selecting what he considers to be the most important 29 papers from this period and reprinting them in this book. Articles by Spearman, Burt, Thurstone, Thorndike, John Anderson, R.B. Cattell, Jensen, McNemar, Barbara Burkes, and others are organized into nine sections—History and Definition of the Concept, Measurement Problems, Developmental Aspects, Types, Analysis of Performance, two sections on Heredity and Environment, Social Class, and Biological Basis. Each section is preceded by an interpretive introduction by Eysenck.

In the final part of the book, Eysenck concludes that the concept, or paradigm (his preferred term), of intelligence has been a fruitful one embracing many divergent facts, that it is quantitative in nature and open to deduction and testing, and that it is perhaps one of the most productive paradigms for psychology in this century. He states that its essential features are best considered at present as "innate, general, cognitive ability."

This stark statement will infuriate many of the social, ethical, and political polemicists who become enraged at the threat to an egalitarian world of any individual differences in performance. But if one follows Eysenck's argument carefully, remembering that intelligence is not a thing but a working concept open to continual investigation and subsequent alteration, the threat disappears; there is room for environmental influence and for alternative hypotheses.

It is time we forgot semantics and returned to our basic scientific task, the measurement of human behavior. One can only hope that the critics of this book, and there will be many, will be objective in their evaluation and follow Eysenck's example in eschewing social, ethical, and political considerations. These are matters demanding much more intricate experimental designs; final answers are best put aside until hard data of the kind "essential in coming to reasonable conclusions" are available.

Eysenck has done a masterful job. Taken together with Matarazzo's *Wechsler's Measurement and Appraisal of Adult Intelligence* (1), which complements it on the clinical side, *The Measurement of Intelligence* offers an orientation to the measurement of intelligence that should satisfy anyone. The Williams & Wilkins Co. is to be congratulated for publishing both.

Evanston, Ill.

Recent Advances in the Biology of Schizophrenia, *by Thomas A. Ban, M.D. Springfield, Ill., Charles C Thomas, 1973, 105 pp., $12.50.*

Dr. Thomas Ban has again demonstrated his special talents—his keen synthetic mind and his urge to set his thoughts to paper. This monograph was developed from lectures delivered by Dr. Ban at the Arizona State Hospital and at McGill University.

Regrettably, the title does not accurately reflect the contents of the book. Dr. Ban has taken research findings mainly from the 1950s and 1960s to construct an overview focusing on biological factors and theories of the etiology of schizophrenia and their interface with biological treatments—especially psychotropic drugs. Conspicuously missing are some of the challenging findings generated by Meltzer's studies of muscle and muscle enzymes (1, 2).

While I commend Dr. Ban for his efforts in digesting and organizing the material contained in some 200 references, the physician or student wishing to be brought up-to-date in biological psychiatry will need to go beyond this monograph.

Opiate Addiction: Origins and Treatment, *edited by Seymour Fisher and Alfred M. Freedman. New York, N.Y., Halsted Press (John Wiley & Sons), 1974, 233 pp., no price listed.*

This volume is based on the December 1972 meeting of the American College of Neuropsychopharmacology. It contains a number of review papers by leading American investigators in the field of opiate addiction. The strongest papers are on the biochemical underpinnings of addiction. It is well edited and referenced like a library reference book. It will provide inter-

ested students an entré into many facets of the literature on addiction.

GEORGE E. VAILLANT, M.D.
Cambridge, Mass.

The Technique and Practice of Intensive Psychotherapy, *by Richard D. Chessick, M.D. New York, N.Y., Jason Aronson, 1974, 369 pp., $12.50.*

This book seems to be aimed primarily at the beginner in psychotherapy in that it skims lightly over a broad range of topics. The reader learns of the pitfalls of a fancy office, especially if it includes a receptionist who loves to chatter and gossip with patients. How the decor and lighting of an office can have an undesirable effect as well as how privacy can be attained without "an expensive soundproofing job" are also proffered as practical tips for the uninitiated.

The entire history of psychiatry, from ancient Hindu texts and Greek prophets through Freud and Bleuler, is reviewed in the first 15 pages of the book. Psychoanalytic theory, deemed the basic science of American psychiatry, is presented in the second chapter from both the individual (Freudian) and the interpersonal (Sullivanian) viewpoints. The value of tranquilizers as adjuvants to the therapeutic process is assayed in four paragraphs, enough to dismiss mood-elevating drugs because they produce side effects and to recommend two minor tranquilizers by trade name while discouraging the use of a third.

Not all of the book is folksy and homiletic, however. One chapter consists of an extensive discussion of Freud's contradictory theories of narcissism, Balint's concept of primary-object love, and the relationship of theory to the psychoanalytic treatment of narcissistic personality disorders. A chapter on metapsychiatry—a term the author claims to have invented—provides an unusually clear description of how destructive, restrictive, and malevolent introjects can be expunged by regression of the ego in the treatment setting.

ROBERT J. CAMPBELL, M.D.
Katonah, N.Y.

Review of Child Development Research, vol. 3: Child Development and Social Policy, *edited by Bettye M. Caldwell and Henry N. Ricciuti. Chicago, Ill., University of Chicago Press, 1974, 557 pp., $15.00.*

The editors state the purpose of this volume clearly and succinctly in their introduction:

> This volume represents a plea for keeping open lines of communication between those whose work has relevance for social action and those who generate and institutionalize such action.

Consciousness raising has encouraged a rapprochement among researchers, child care practitioners, and society at large. Three themes recur in many of these chapters, each of which deals with important areas of research and their applications. First, words of caution are iterated concerning the premature application of inconclusive and insufficiently validated research findings. Second, the complexity of human relationships precludes the prevention or remediation of developmental arrests and maladaptive behaviors by simple educational measures or environmental manipulations. Third, intervention and remediation have to be based on a thorough knowledge of developmental milestones, an accurate assessment of the mutual relationships between parent and child, and an appreciation of socioeconomic and cultural realities and differences.

Mary Ainsworth's chapter on the "Development of Infant-Mother Attachment" is a well-written, comprehensive review of studies on the precursors of infant-mother attachment, the critical factors and phases for its successful establishment, and the various noxious effects of mother-child separations during the first years of life. In her summary she draws 11 inferences of great importance for practitioners working with children and mothers.

Leonard Berkowitz' "Control of Aggression" reviews factors likely to promote aggressive behavior and those apt to curb its primitive expression. He states that low tolerance for frustration and a high level of anxiety easily lead to aggressive action. A proper balance between frustration and gratification in a consistent and warm parental climate that provides opportunities for learning nonaggressive responses to frustration is the best safeguard against violence.

Elizabeth Herzog and Cecelia Suda conclude from their review of "Studies on Children in Fatherless Families" that the blanket generalizations made about consequences of the father's absence can probably be rejected and that the impact of the father's absence as a discrete variable in itself cannot be researched successfully.

In "Social Class and Development," Cynthia Deutsch points out the complexity of the concept of socioeconomic status and describes the consequent methodological and conceptual problems encountered in social-class developmental studies. She makes an eloquent plea for more exacting analysis of data and interrelationships and for a focus on the whole environment as it interacts with the organism.

The chapter on "Operant Behavior Modification" by Todd Risby and Donald Baer offers a comprehensive review of the theory of operant conditioning and its technical application for developing, reinforcing, extinguishing, or modifying behavior.

Among several important observations and recommendations in "Effectiveness of Environmental Intervention Programs" by Frances Horowitz and Lucile Paden are that intensive individualized programs for infants and young children are likely to produce the most impressive results and that more structured and educationally oriented preschool intervention programs show strong gains. The authors make a fervent plea that the government consider needs rather than costs in its funding of interventive programs.

In "Programs for Disadvantaged Parents" by Catherine Chilman, several important implications drawn from an excellent survey are summarized, e.g., parent education programs are of limited practicality and effectiveness; basic income maintenance is essential for any program that seeks to deal effectively with disadvantaged parents and children; and no satisfactory standardized instruments to measure change in parental attitudes have been developed.

The chapter on "Adoption" by Edmund Meek and that on "The Child and the Law" by Margaret Rosenheim give both historical information on current philosophies and policies governing adoptive practices and on existing laws dealing with child abuse, parents' rights, and juvenile delinquency.

It is impossible to do justice in this short review to the rich and thoughtful content of this volume. I strongly recommend that it be read by all those who have a vital interest in preventive and rehabilitative services for children and families.

Successful Aging: A Conference Report, *edited by Eric Pfeiffer, M.D. Durham, N.C., Duke University Center for the Study of Aging and Human Development, 1974, 149 pp., $5.00 (paper).*

This volume represents the papers given at a conference titled "Successful Aging" held at Duke University on June 7–9, 1973. The conference was sponsored by the Older Americans Resources and Services Program of the Duke University Center for the Study of Aging and Human Development. It was supported in part by the Administration on Aging, a social and rehabilitation agency of the U.S. Department of Health, Education, and Welfare.

Most of the papers are brief and do not cover the subjects in depth. They give hints as to how one can age more successfully than by simply leaving matters to chance. Jennie Keith-Ross, an anthropologist, contributes a most interesting paper on successful aging in a retirement residence in France.

Many of the articles are anecdotal in nature and many case histories are presented. This report is recommended for those who wish to know the opinions and experiences of some of today's clinicians and research workers in the ever-expanding field of research on aging.

JOHN A. BUEHLER, M.D.
Kentfield, Calif.

Research Advances in Alcohol and Drug Problems, vol. 1, *edited by Robert J. Gibbins, Yedy Israel, Harold Kalant, Robert E. Popham, Wolfgang Schmidt, and Reginald G. Smart. New York, N.Y., John Wiley & Sons, 1974, 374 pp., $22.00.*

The primary goal of this series of annual volumes will be the presentation of evaluative papers on significant topics regarding the drug problem from an interdisciplinary viewpoint, an approach "widely advocated but seldom practiced," according to these editors. This first volume, edited by senior scientific staff members of the prestigious Addiction Research Foundation of Ontario, consists of eight chapters of literature reviews of recent research advances. These cover several disciplines, including biology, chemistry, psychology, epidemiology, and clinical studies.

One chapter, titled "Animal Models for the Study of Drug Abuse," attempts to summarize "the conceptual framework for analyzing the behavior of self-administering drugs." The authors of this article use the concepts derived from studies based largely on operant conditioning and suggest the extrapolation from animal studies to human drug behavior.

Another chapter, "Clinical Pharmacology of Marihuana" by Leo Hollister, offers a general and evaluative review of the latest research on marijuana. Most of the articles comment on pertinent problems connected with investigative efforts and offer corrective suggestions for the future. Several papers mention the commendable purpose of trying to make some coherent sense out of the expanding and overlapping literature about the particular topic covered.

As a clinician, I was quite impressed with George Henry's "Treatment and Rehabilitation of Narcotic Addiction." Dr. Henry covers detoxification, opioid maintenance, the antagonistic drugs, psychosocial approaches (e.g., Synanon), and the results of treatment. He concentrates on the critical aspects of recent developments—exactly what is needed to keep abreast of what is significant in the burgeoning literature. Two statements from this chapter are worth quoting:

> We do not know whether most [treatment methods] are better than no treatment at all. . . . We do not know what happens to drug dependent persons who are not treated or incarcerated.

Another excellent paper, "The Epidemiology of Psychoactive and Hallucinogenic Drug Use," is a descriptive essay that surveys methodological difficulties, morbidity and mortality associated with drug use, and the characteristics of drug users. It also offers some definitive conclusions and research directions.

The entire volume represents high-quality efforts at condensing and clarifying advances in drug research. Although the jacket states, "This book focuses on drug addiction," at least one-third of the book is concerned with alcohol. It should be a good reference volume for anyone searching for the latest material for teaching or research. The bibliographies are extensive—one chapter alone has 540 references. Finally, special mention should be made of the excellent 50-page index that greatly increases the book's usefulness.

MANUEL M. PEARSON, M.D.
Philadelphia, Pa.

Psychiatric Diagnosis, *by Robert A. Woodruff, Jr., M.D., Donald W. Goodwin, M.D., and Samuel B. Guze, M.D. New York, N.Y., Oxford University Press, 1974, 212 pp., $7.95; $4.95 (paper).*

This well-researched and well-organized book deals in some detail with the various diagnostic entities seen in the clinical practice of psychiatry. In their introduction, the authors point out:

> There are many diagnostic categories in psychiatry, but few are based on a clinical literature where the conditions are defined by explicit criteria and follow-up studies provide a guide to prognosis. Lacking these features, such categories resemble what sociologists call labeling.

Simple labeling is avoided in this book. The authors show the usefulness of diagnosis based on specifically defined criteria in planning treatment and predicting outcome of illness.

Each chapter is divided into several sections, including definition, historical background, epidemiology, clinical picture, natural history, complications, family history, differential diagnosis, and clinical management. Statements are well documented with references to the psychiatric literature, and the bibliography at the end of each chapter is extensive. At the end of the book there are two appendices, one in support of the medical model of psychiatric illness and the other a summary of diagnostic criteria for use in psychiatric research.

PETER M. ZEMAN, M.D.
Hartford, Conn.

Disordered Thought in Schizophrenia, *by Loren J. Chapman and Jean P. Chapman. New York, N.Y., Meredith Corp. (Appleton-Century-Crofts), 1973, 347 pp., $15.00.*

The Chapmans have done an excellent job of presenting and summarizing the leading theories on disordered thought in schizophrenia. They pose a direct challenge to Arieti's *Interpretation of Schizophrenia* (1) in such statements as the following:

> Von Domarus and Arieti erred in that the laws of Aristotelian logic are not the laws of thought and are not even the laws of most reality-oriented adaptive thought. (p. 188)

This book discusses the evidence for a number of theories concerning the nature of schizophrenic thought disorder. Much of the book is devoted to the problem of identification and measurement of cognitive symptoms as a reflection of disordered thought. The Chapmans critically analyze the methodological problems in research regarding the selection of schizophrenic subjects, measurement of disordered thought, and research designs. They report that most of the available research evidence on theories of schizophrenic disorder fail to use the most appropriate design for measuring cognitive deficit of matched tasks in order to delineate the subvarieties of schizophrenic thought disorders.

The authors present the leading theories on disordered thought in schizophrenia carefully and historically, beginning with Bleuler's theory of broken associative threads. They describe the theories of excessive yielding to normal biases, loss of abstract thinking, errors in syllogistic reasoning, and the phenomenon of overinclusion. They also discuss regression to an early stage of development in psychoanalysis, schizophrenic thought disorder as a phase in response to emotional problems, the Shakow formulation of loss due to a major set, defects in attention and information processing, the drive theory, schizophrenic cognition, and theories based on schizomimetic conditions. They emphasize the heterogeneity of schizophrenia as the basic clinical reality of schizophrenic thought disorders.

The authors are trying to clear a field through the jungles of schizophrenic research for further objective study. They have come to three tactical conclusions. These are not startlingly new but will be helpful in redirecting the attention of researchers, clinicians, teachers, and students of schizophrenia to the following efforts: 1) determining the different kinds of thought disorders in schizophrenia, 2) using measures of thought disorder to compare different kinds of schizophrenic patients with one another, and 3) discovering the subgroupings of patients within schizophrenia. (The authors' differential discussion of process and reactive schizophrenia, for instance, is exemplary.)

One other strategic conclusion they come to is that the "investigation of a possible schizophrenic defect in information processing seems promising." I agree with this statement, which points to a very fruitful approach. The apparent schizophrenic verbalizations are but a final common pathway of a manifestation of information distortion that can occur at a genetic cellular biochemical level or as a psychosocial distortion of consciousness and communication.

The literature search and references in this book are extensive, but they fail to include more sophisticated nonclinical models of biochemical, neurophysiological, communicational, or cybernetic system theories, apart from the Broadbent model. The authors remain naturally biased in favor of the clinical psychological approach.

I believe that the Chapmans may be overstating their case when they claim that "investigators can solve the problem if they use appropriate research designs and properly chosen patients." It is quite possible that the solution to the enigma of schizophrenia may come from outside of the clinical research of schizophrenic patients.

The puzzle of schizophrenic thought might remain unsolved if we do not gain further understanding of the neurophysiological process of normal thinking—the interaction of system function and information within the brain. Nevertheless, I recommend this book not only as a good reference for clinical researchers and practitioners but also as a fine textbook for a survey course for psychiatric residents and graduate students studying disordered thought in schizophrenia.

Camping Therapy: Its Uses in Psychiatry and Rehabilitation, *edited by Thomas Power Lowry, M.D. Springfield, Ill., Charles C Thomas, 1974, 132 pp., $7.75.*

This collection of 18 articles describes camping programs for normal as well as emotionally and physically disordered children and adults. Each chapter is brief; many contain short case reports.

Providing mental health care in more natural environments to promote integrity and growth has been a relatively neglected subject in psychiatry. Yet the pressures of technological society and its dehumanizing institutions cause many emotional casualties. This strongly suggests rich therapeutic possibilities in camping and its more basic lifestyle.

This book reflects the infancy of camping therapy. It is a brief introduction to its practice and possibilities. The few references to the literature are, for the most part, dated. Several chapters are redundant, and the issue of reentry from the less structured camp setting back into the pressures of civilization (1) is essentially neglected. Camping therapy is clearly fun for patient and staff alike; however, controlled studies and follow-up data are needed to evaluate whether it is effective, how costly it is in relation to its benefits, and what types of patients respond favorably to it.

Rorschach Responses in Old Age, *revised ed., by Louise Bates Ames, Ph.D., Ruth W. Métraux, M.A., Janet Learned Rodell, Ph.D., and Richard N. Walker, Ph.D. New York, N.Y., Brunner/Mazel, 1973, 211 pp., $12.50.*

This is a revised edition of the volume of the same name originally published in 1953. The changes between editions consist of the insertion of a page and a half of material on scoring whole responses, an increase from 8 to 61 in the number of persons retested, the deletion of several individual case examples to make room for a new short chapter on supplementary tests, and the addition of 10 new citations to the references.

Of the 200 aged persons whose tests form the basic data in this book, 140 were women. Most of the sample were well educated, of upper- and upper-middle-class socioeconomic status, and between 70 and 100 years old. The Rorschach test was administered in the same way these researchers have given it to children (1). The cards were shown only once and inquiries were gathered immediately following a response.

On the basis of scores approximating those expected of normal younger adults and in the absence of certain qualitative

signs, the authors classed 20 percent of the records as normal, 70 percent as presenile, and 10 percent as senile. Because of the authors' thesis that old age is "reverse growth," they were surprised that such a large percentage of their subjects could be classed as normal on the basis of their Rorschach performance. However, it seems to me and to others who have studied aged persons in the 20 years since the first edition of this volume appeared that the presenile group merit the most attention.

Both the number of persons classified in this book as presenile and the descriptions of their performance suggest that subgroups exist within this larger group. Two of the features attributed to presenile individuals—garrulousness and repetitiveness—have been noted by other researchers. In this book Ames and associates give vivid descriptions of the transactional impact that presenile behavior has on others.

The weaknesses of the book lie in its oversimplification of old age as a period of reverse growth and its efforts to locate individual aged persons at a single behavior level or level of intactness rather than using such concepts as dimensions or domains of behavior. The latter permit reference to complex interactions among traits, skills, functions, and decrements.

The authors' findings are far more complex and fascinating than their concepts of levels. The merits of the book lie in the qualitative sign checklists devised by the authors. One list of signs consists of those found in childrens' Rorschachs that do not appear in Rorschachs of normal adults. A second list of signs is composed of those which the writers feel do not characteristically appear in either normal adults' or normal childrens' records. These checklists become central in ordering the findings of this research.

In summary, one can recommend the sign checklists devised by the authors to quantify the qualitative features of Rorschach performance in aged persons without endorsing some of the theoretical underpinnings of the volume. This book had much to offer when it first appeared 20 years ago and still does.

Basic Concepts of Psychoanalytic Psychiatry, *by Elizabeth R. Zetzel, M.D., and W.W. Meissner, M.D. New York, N.Y., Basic Books, 1973, 305 pp., $10.00.*

Dr. Zetzel was engaged in collaborating on this book at the time of her sudden death in November 1970. Dr. Meissner had undertaken the task of rewriting, revising, and expanding lectures that Dr. Zetzel had presented in a series of seminars and public lectures in Boston over a span of several years to present a coherent and integrated account of the psychoanalytic perspective. As the draft of each chapter was finished, Dr. Zetzel read and commented on possible changes. This process had been completed for the first 13 chapters at the time of her death. She had the final 3 chapters in hand and had made some comments about them to Dr. Meissner, but she had not reviewed them as completely as she had the others.

Drs. Zetzel and Meissner define the basic structure of this book as an account of the developmental process, including its inherent potentialities for progressive adaptation and regressive retrenchment. There is an integration of the dynamic, economic, structural, and adaptational points of view in this setting.

This volume might be viewed as a beginning textbook in psychoanalytic psychiatry for psychiatric residents and allied personnel. It is a courageous attempt to weld together the various phases of Freudian psychoanalytic theory, more recent developments in ego psychology, the concepts of interpersonal theory and adaptational psychoanalysis, and some of the clinical observations in child development as well as in sleep and dream research.

Such integration is a difficult task; no great measure of success is seen in these pages. Most of the material is devoted to tracing Freudian theory chronologically through the energic and structural contexts. The authors note that Freud heralded the importance of adaptation on many occasions. Chapter after chapter is devoted to Freudian theory; they cover anxiety, repression, and their interaction, primary and secondary process, and the developmental hypothesis, to name a few.

The greatest number of references in the short bibliography (71 entries), after Freud, are to Erikson and David Rapaport. Hartmann and Kris are mentioned once. There are a number of references to contributions by various workers in the text that are not included in the bibliography, e.g., Kris's regression in the service of the ego and the sleep research of Aserinsky and Kleitman. In the latter context, neither Fisher nor Dement is even mentioned. There is also no allusion to Sandor Rado in the discussion of adaptational psychoanalysis.

My impression is that the authors were torn between pursuing their goal of a coherent and comprehensive account of psychoanalytic psychiatry and becoming liable to charges of apostasy in psychoanalytic thinking. Some of the writing is heavy and obscure—much less clear than the good translations of Freud and never approaching the style and conciseness of Erikson.

Although the final three chapters were not fully reviewed by Dr. Zetzel, she approved their inclusion in principle. Each of the chapters, titled "Neurotic Development and Analyzability," "An Approach to the Borderline Patient," and "Psychoanalysis As Therapy," presents a fitting topic for another volume. However, each is necessarily given only superficial treatment and could be a source of confusion to the young psychiatrist.

JAMES P. CATTELL, M.D.
New York, N.Y.

The Depressed Woman: A Study of Social Relationships, *by Myrna M. Weissman and Eugene S. Paykel. Chicago, Ill., University of Chicago Press, 1974, 279 pp., $10.00.*

This book describes an exploratory study in which 40 women with acute depression but with no physical illness or psychosis were compared with 40 women who were considered normal, i.e., free from psychiatric and physical illness. The two groups were matched as to age, religion, ethnic origin, and neighborhood. The social relations and symptomatology of both groups were studied at regular intervals over a 20-month period in the clinics of Yale University and Tufts University.

Treatment for the depressed women included the use of an antidepressant (amitriptyline) as well as psychotherapy and counseling. Interview and questionnaire techniques were used in addition to the standard clinical interview. Six aspects of the subjects' behavior were rated: behavior and performance at work, during leisure time, in the extended family, in the marital role, in the parental role, and in the family unit. Factor analysis and correction for reliability and validity were carried out.

The results of this study clarify many of the conflicting ideas about depressed women that have been reported. This study

found that although these depressed women were moderately impaired in their daily lives and interpersonal relationships, their marital relationships became the arena for the depression. Friction, poor communication, dependency, and diminished sexual satisfaction were evident. Acutely depressed women showed an increase in hostility, especially toward their husbands and children. Remission of symptoms and improvement in social adjustment were more rapid during the first 2 months of the 20-month treatment period.

The normal subjects, by comparison, were well adjusted and experienced housework as satisfying, parent-child relations as warm and involved, and marriage as affectionate and harmonious.

The authors of this book are to be congratulated for their clear presentation of this carefully controlled research study. This work should serve as a reliable frame of reference for further research, not only of depression, but also of normal subjects. This book should be of real value to all those who are involved in the day-to-day care of depressed women.

HELEN B. CARLSON, M.D.
Downey, Ill.

Electroencephalography (EEG) of Human Sleep: Clinical Applications, *by Robert L. Williams, M.D., Ismet Karacan, M.D., D.Sc., and Carolyn J. Hursch, Ph.D. New York, N.Y., John Wiley & Sons, 1974, 164 pp., $15.00.*

This book is a summary of about a decade of intensive work at the sleep laboratories of the University of Florida. The data represent over 6,000 all-night sleep EEGs on hundreds of normal subjects aged 3 to 80 who slept in the laboratory on successive nights. The purpose of the work was to develop an electrographic (EEG and eye-movement) atlas of normal sleep. The reader is given a variably adequate account of the laboratory procedures and equipment, which is critical for an understanding of the resultant tracings.

The extensive bibliographies at the end of each chapter identify supplemental reading. In the foreword, Dement likens the data on sleep recorded in this book to the familiar height-and-weight growth charts. He states that the data add a new dimension to the assessment of normal development.

Sleep EEGs are recorded at a chart speed of 15 mm/second, which results in 1,000 or more pages a night for each patient. Some sort of data reduction is imperative, so the records are scored by one-minute epochs. This yields hundreds of scores for each night of sleep. Fortunately, it has been known since the 1930s that there is a more or less steady progression through the various stages of sleep. This permits classification of large blocks of time into pattern stages. Sleep researchers have achieved a moderate consensus about the criteria for stages 1 through 4 and for the REM stage.

There is less agreement regarding number and placement of electrodes. This book, although written by researchers at one laboratory, shows a variability that complicates the understanding of illustrative sleep stages. There is also a puzzling tendency for recorded eye movements to be of variable phase and of higher voltage on the left side.

This atlas is meant to be useful to a wide range of professionals, who need a clear display of the electrographic features of the sleep stages that would constitute a standard against which their own material could be rated. Such pattern recognition is very substantially handicapped when the figures showing the data are printed at a reduced scale. Indeed, two different scale reductions are used in this book, and the degree of reduction is not really precisely stated for either. The elimination of redundant labels and wasted white space in this book could have resulted in slightly shorter time samples that could have been displayed life-sized and therefore been much more useful to the reader wishing to adopt this classification system. To the degree that such illustrations are important, as they are in EEG, book size would better be adapted to figures than to text.

The main and unique contribution of this work is contained in a long sequence of admirably clear tables and figures. From these one can determine time in bed, time from onset of sleep to final awakening as well as the percentage of this time spent in actual sleep, sleep onset latency, a sleep efficiency index, the proportion of time spent in each stage of sleep, and the duration of each such sleep stage. The tables and figures also show the appropriate statistical handling of this mass of data. Further, each of these categories is detailed by age groups, which are further contrasted as to sex. (The latter differences are largely nonsignificant.) The illustrative material is ingeniously plotted and easy to understand. The REM phenomena receive explicit treatment.

How is the clinician to use this information in the diagnosis and treatment of the patient with a sleep disorder? One chapter of the book is devoted to the dyssomnias, which, together with headache, must comprise man's most benignly annoying discomforts. The enthusiasm of the authors for all-night sleep studies is not substantiated by present applications to most of the dyssomnias, however. There are some specific exceptions (epilepsy, narcolepsy, Kleine-Levin syndrome, and Pickwickian syndrome) where sleep EEG is indeed useful, although all-night sleep study is rarely required.

The concluding chapter on future directions touches on the likelihood that biochemical variables will be important in sleep research. Stage 2 sleep, which makes up half of our sleep throughout life, also needs investigation. No doubt jet lag will be studied; it may be necessary then to record in homes, hotels, and airports. Also to be studied is the overwhelming drowsiness that occurs while one is sitting upright in a lecture hall. The authors recognize the fact that for these and other problems much help will be needed from computers.

My final regret about this book is given with the hope that authors, editors, and publishers may yet mend their ways and present material so it is maximally easy to read and understand. I refer to the problem of reference citation within text. In this volume, references are identified by names and year, generally with the inclusion of all (up to six) authors and only occasional use of a welcome "et al." The use of the latter is not related to the number of authors. Since much sleep research appears under multiple authorship, and since many of the names are double- and even triple-hyphenated, the reader must scan through a veritable thicket of names and numbers to reach the text. There is a better way, and the resultant savings in cost and paper could be contributed to improved display of the primary electrographic data.

CHARLES E. HENRY, PH.D.
Cleveland, Ohio

The Administration of Mental Health Services, *edited by Saul Feldman, D.P.A. Springfield, Ill., Charles C Thomas, 1973, 383 pp., $18.75.*

The editor of this book attempts to compile the thinking of a number of persons whose expertise in the generic aspects of administration and whose specific knowledge of the mental health

field qualify them to adapt the principles of general administration to the field of mental health.

The primary point of the book is that administration in the mental health field is so modified by the environment in which it is applied that it is a specialized and individualized field of its own. In my opinion, inadequate emphasis is given to the fact that the principles of sound administration are generalizable; it is merely the technique of application of these principles that requires modification.

The book states that mental health professionals, by training and by nature, fight the restriction and systematization of a strong administrative organization. While discipline within their practices may be well established, their lack of discipline in regard to established administrative procedures makes them a difficult group with which to cope.

The book focuses on the field of government-funded mental health programs; little or no attention is paid to the private and proprietary areas of mental health. The various authors discuss the tremendous growth in size and complexity that has occurred in the mental health field and point out the obvious gap that develops when administrative procedures such as budgeting, personnel management, financing, and management information do not catch up. However, they do not offer many solutions except to say that the overall field of mental health administration needs more emphasis.

This book could serve as a sourcebook for readings in the area of mental health administration, but it is not the basic text that the jacket suggests it to be.

Submission of New Research Abstracts for the 1975 Annual Meeting, May 5–9, Anaheim, California

The 1975 annual meeting will again include a series of two New Research sessions. Those interested in presenting papers at these sessions should obtain an abstract form from the Office of the Chairman of the Program Committee, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. It is not necessary to supply the full text of a paper submitted for consideration for New Research sessions. Completed abstracts must be received in the Office of the Chairman of the Program Committee by March 1, 1975.

This Month's Reviewers

FELIX F. LOEB, JR., M.D., is Assistant Clinical Professor of Psychiatry, University of California, San Diego, Calif.

JAMES Q. SIMMONS III, M.D., is Chief of Child Psychiatry and Associate Program Director, Mental Retardation and Child Psychiatry Program, Neuropsychiatric Institute, University of California, Los Angeles, Calif.

EVELYN S. MYERS is Managing Editor of this journal and Coordinator, Psychiatric Care Insurance Coverage, APA.

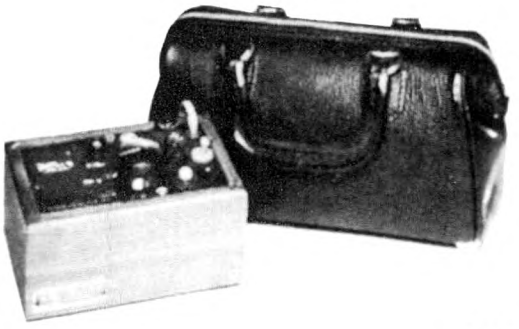
MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

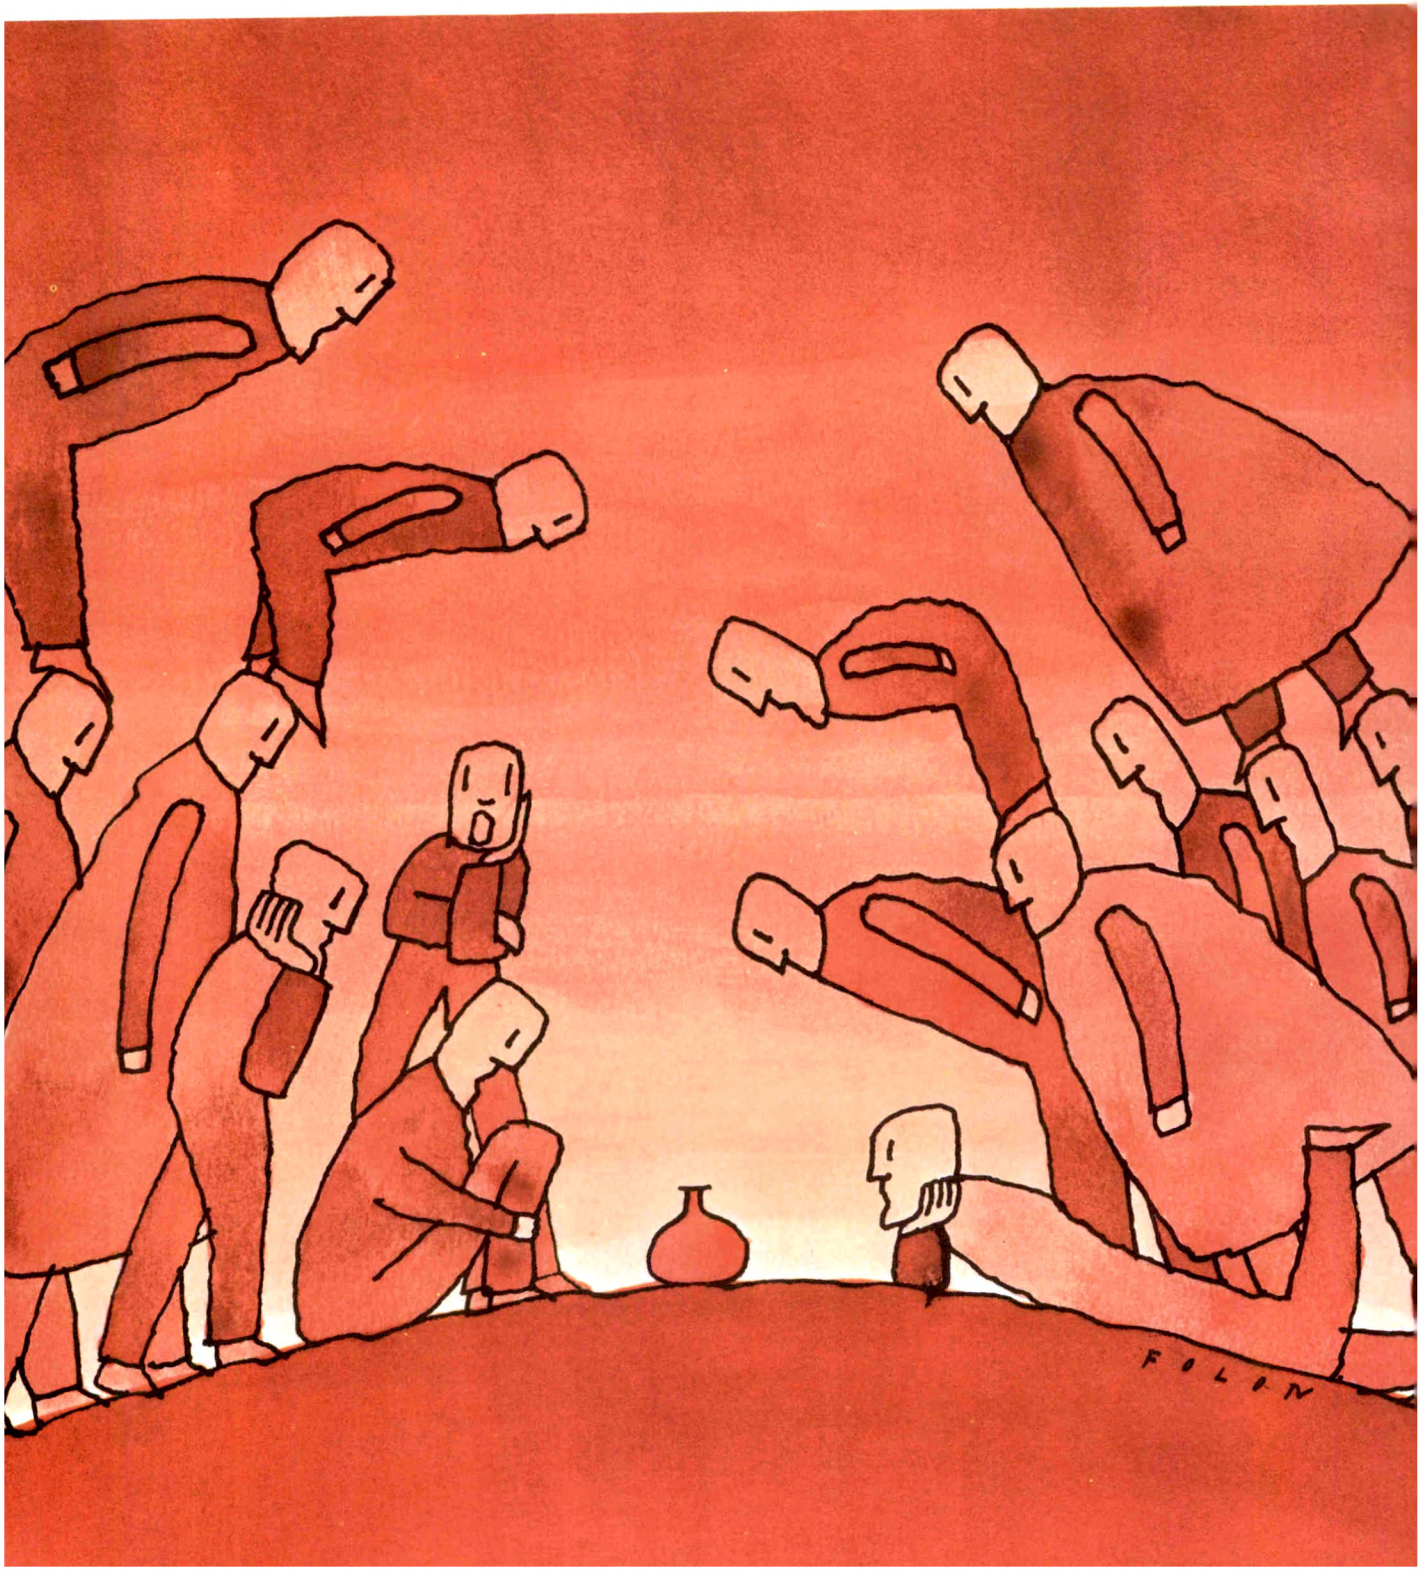
Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.



Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

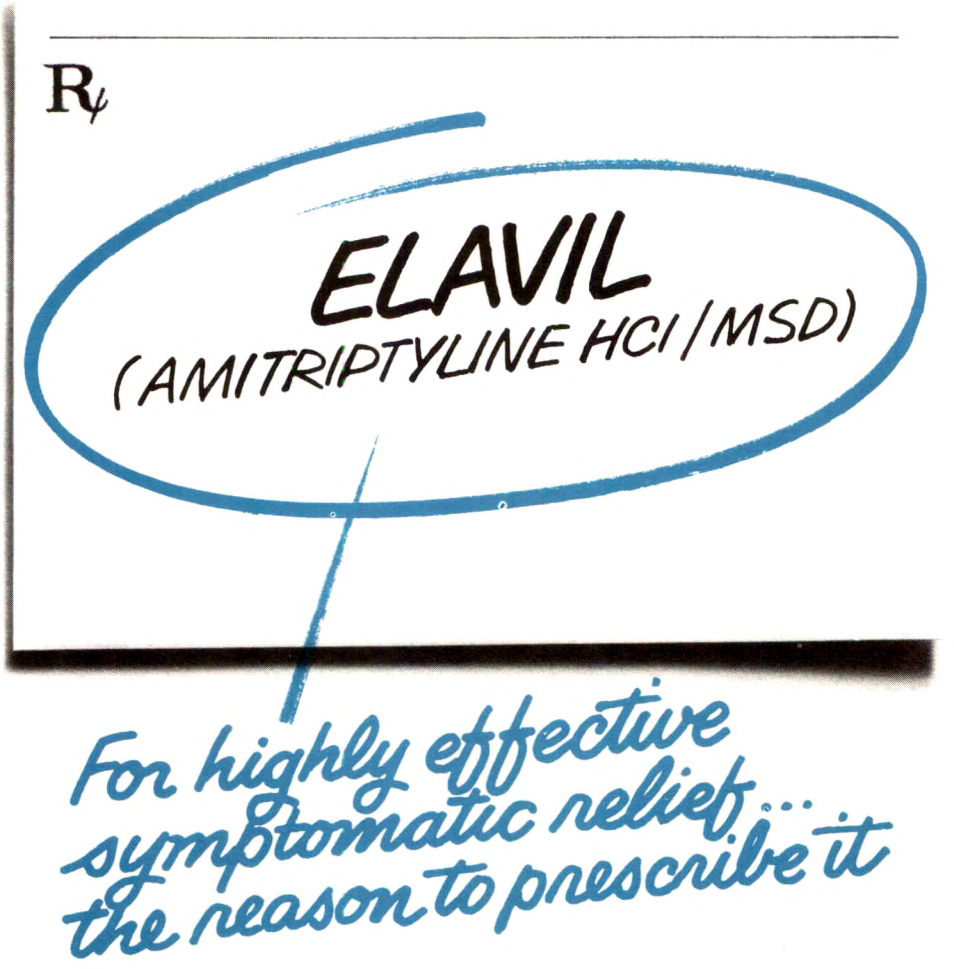
The long wait for low priced imipramine ends

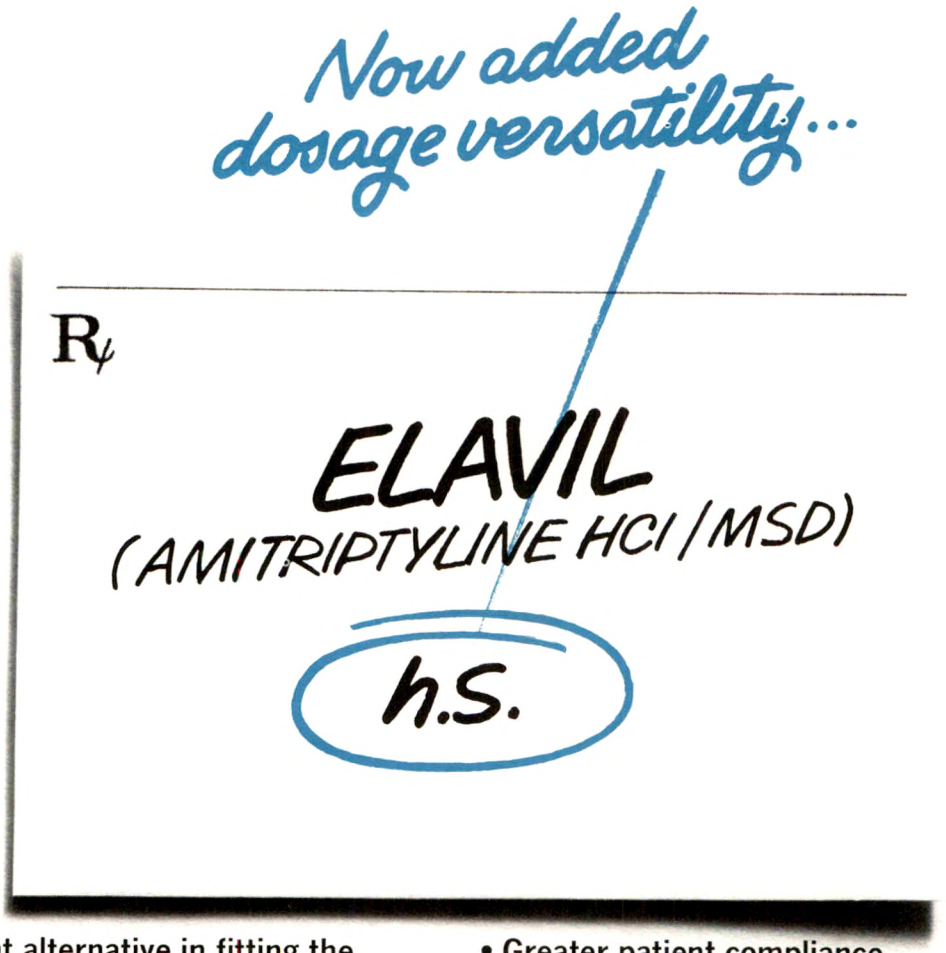
Introducing low cost

SK-Pramine™
brand of
imipramine HCl

Tablets: 10 mg., 25 mg., 50 mg.



- Brand name quality you can depend on.
- Savings your patients can bank on.



SK
SK-LINE®
SK&F Quality at Low Cost
Smith Kline & French Laboratories
Div. of SmithKline Corp., Phila., Pa.

*The manufacturer's suggested list prices to pharmacists for 'SK-Pramine' compared to those for Tofranil® (imipramine HCl, Geigy). Differences in pharmacy charges for these products will vary, depending on location, services offered, and other factors.

In the treatment of clinically significant depression...

- **An important alternative in fitting the medication to the patient's needs**

  Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. Of course, ELAVIL may be administered two, three, or four times as well as once a day. This dosage versatility allows prescribing precisely for the patient's needs.

- **Once-a-day dosage schedule for adult outpatients**

  Therapy should be initiated with 50 mg to 100 mg at bedtime. This may be increased by 25 or 50 mg added to the bedtime dose as necessary to a maximum daily dose of 150 mg. The usual maintenance dose is 50 to 100 mg a day given at bedtime, though in some patients, 40 mg per day is sufficient.

- **Greater patient compliance**

  The simplicity of once-a-day dosage at bedtime makes it easier for patients to adhere to a regimen—an especially important consideration in depressed patients whose self-motivation may be at a low ebb.

  Should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

once a day at bedtime

Please see addendum on following page for other details of dosage and administration including divided daily doses, dosage in hospitalized patients, and dosage in elderly and adolescent patients.

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

added dosage versatility in clinically significant depression

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of tricyclic antidepressant poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

addendum

MSD
MERCK SHARP & DOHME

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for initial therapy in adult outpatients. Starting dosage is usually 75 mg daily in divided doses or 50 to 100 mg once a day at bedtime. If necessary, this dosage may be increased gradually to a total of 150 mg a day. When doses are divided, dosage increases are made preferably in the late afternoon or at bedtime. A sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

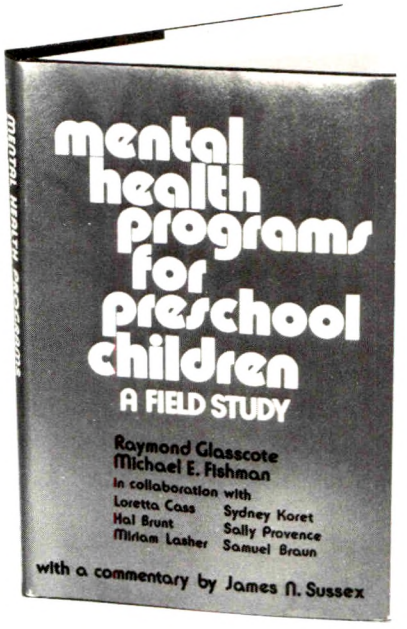
50 mg (beige)

The 50-mg tablet may be advantageous whenever higher dosages are required, or when the single daily dose is given at bedtime. The 50-mg tablet may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

INJECTION
10 mg per ml



For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.

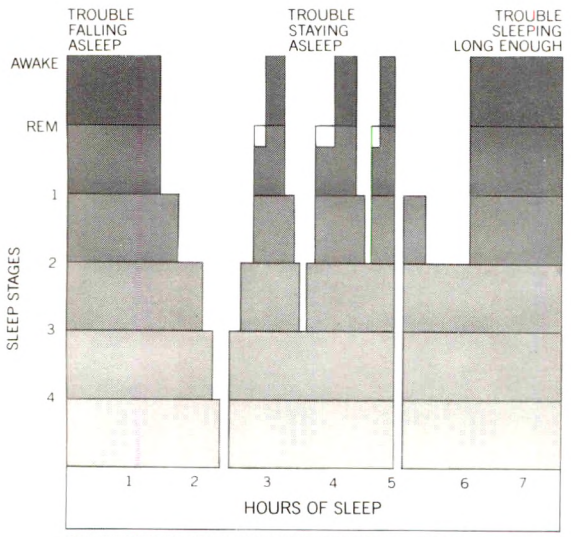
Basic considerations in the management of insomnia...

Prescribe sleep medication at the lowest effective dose...

When you determine that sleep medication is indicated for a patient with insomnia, individualize dosage. In some cases, especially in mild insomnia or elderly or debilitated patients, lower than usual dosage may effectively relieve symptoms. As patient contact is maintained during treatment, dosage can later be titrated according to individual response.

Treat pharmacologically only as long as necessary...



Sleep medication should usually be considered a limited course of treatment. Whether insomnia is transient or chronic, chemotherapy should end as soon as possible. In this light, the number of prescription refills should depend on your evaluation of the patient.

Select an agent known to be relatively safe, and effective for the presenting type of insomnia...

Dalmane (flurazepam HCl) is useful for the three most common types of insomnia (see composite sleep profile). On average, Dalmane provides sleep within 17 minutes that lasts 7 to 8 hours with few nighttime awakenings.[1-4] Also, Dalmane 30 mg (the usual adult dosage) has been shown consistently effective during 14 consecutive nights of administration without increasing dosage.[5]

Dalmane is relatively safe and generally well tolerated; morning "hang-over" is infrequent. In the elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness or ataxia.

COMPOSITE PROFILE OF THREE COMMON TYPES OF INSOMNIA

Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

Released from symptoms of psychotic depression...

Productive again.

By helping to reduce the frequency and intensity of psychotic symptoms, Navane (thiothixene) often permits resumption of more normal, more productive living.

The antipsychotic effectiveness of Navane—with relatively little drowsiness—helps patients remain more active, more alert, better able to meet the ordinary demands of life.

Cardiovascular side effects such as hypotension and nonspecific EKG changes are relatively rare with Navane (thiothixene). Extrapyramidal symptoms have been reported, but are usually controlled by reduction in dosage and/or administration of antiparkinson drugs.

Once you've controlled acute psychosis or psychotic depression, some patients can be maintained on a simple once-a-day dose. This once-a-day regimen can reduce the risk of missed doses with no loss of efficacy.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Navane®

(thiothixene) (thiothixene hydrochloride)

Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg./Concentrate 5 mg./cc.

Once-a-day–to help control symptoms of psychosis

For prescribing information, including adverse reactions and contraindications please see following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. **Concentrate: 5 mg./cc.** **Intramuscular: 2 mg./cc.**

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. (thiothixene hydrochloride)
Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane (thiothixene), there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg./kg./day), rabbits (3 to 50 mg./kg./day), and monkeys (1 to 3 mg./kg./day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS-depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane (thiothixene) may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane [thiothixene] for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis), have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane (thiothixene hydrochloride) Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the midlateral thigh.

The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower- and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following reactions have been reported with Navane. However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane (thiothixene) is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur, although it usually subsides with continuation of Navane therapy. The incidence of sedation appears to be similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: Although not reported with Navane, certain antipsychotic agents have been associated with persistent dyskinesias. Tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane (thiothixene) have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration because safe conditions for its use have not been established.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Usage in children under 12 years of age is not recommended.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of behavior is desirable, the intramuscular form of Navane (thiothixene hydrochloride) may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg. of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg./day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules: Navane Concentrate—In milder conditions, an initial dose of 2 mg. three times daily. If indicated, a subsequent increase to 15 mg./day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg. twice daily.

The usual optimal dose is 20 to 30 mg. daily. If indicated, an increase to 60 mg./day total daily dose is often effective. Exceeding a total daily dose of 60 mg. rarely increases the beneficial response.

Some patients have been successfully maintained on once-a-day Navane (thiothixene) therapy.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg., 2 mg., 5 mg., and 10 mg. in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg. of thiothixene, in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 cc. (4 oz.) bottles with an accompanying dropper calibrated at 2 mg., 4 mg., 5 mg., 6 mg., 8 mg. and 10 mg. Each cc. contains thiothixene hydrochloride equivalent to 5 mg. of thiothixene. Contains alcohol, U.S.P. 7.0% v/v. (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular Solution is available in a 2 cc. amber glass vial in packages of 10. Each cc. contains thiothixene hydrochloride equivalent to 2 mg. of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v.

New APA Task Force Reports

Behavior Therapy in Psychiatry

This comprehensive report reviews the historical development of behavior therapy, its efficacy for the treatment of psychiatric problems, its current forms and uses as well as potential abuses, and its relationship to dynamic psychiatry. Approved for publication by the APA Council on Research and Development, the Report was prepared by a Task Force comprising Lee Birk, M.D., John Paul Brady, M.D., Alan J. Rosenthal, M.D., W. Douglas Skelton, M.D., Joseph B. Stevens, M.D., and Consultants Stephanie B. Stolz, Ph.D., Joseph V. Brady, Ph.D., Arnold A. Lazarus, Ph.D., James J. Lynch, Ph.D., and Edwin J. Thomas, Ph.D.

Report No. 5 — 75 pages, June 1973 — Single copy $3.50

Patterns of Private Psychiatric Practice

The Present and Future Importance of Patterns of Private Psychiatric Practice in the Delivery of Mental Health Services

This report marks the first formal statement the Association has ever issued delineating the vital role of its private practitioner members in the delivery of mental health services in the U.S. Contains sections on patterns of private practice, the economics of it, the impact of third party payments on it, its relation to the public sector, and an assessment of the overall contribution of the private sector to the treatment of mental illness. Stresses the theme that any national system for the delivery of mental health services must be a "balanced mix" of both the private and public sectors, each reinforcing the other. Approved for publication by the Council on Mental Health Services, the Report was prepared by a Task Force comprising Drs. Ewald Busse, Rogers J. Smith, Reed S. Andrus, Winston Cochran, Albert A. Lorenz, Robert L. Leopold, Louis W. Nie, and Consultants Alan I. Levenson, Zigmond M. Lebensohn, Walter E. Barton, and Mr. Robert L. Robinson.

Report No. 6 — 29 pages, June 1973 — Single copy $2.00

Megavitamin and Orthomolecular Therapy in Psychiatry

This comprehensive report reviews and evaluates claims for the effectiveness of the megavitamin rationale, clinical trials of NA and NAA with criticisms and attempts at replication, early clinical trials and attempts at replication, pellagra, schizophrenia and the question of NAD, the diagnosis of schizophrenia, patient selection, and specific phase-treatment programs of orthomolecular psychiatrists, quantitative aspects of megavitamin therapy, incompatibility of Methyl-receptor and NAD positions, and toxicity. Published with the approval of the Council on Research and Development, the Report was prepared by a Task Force comprising Drs. Morris Lipton, Thomas A. Ban, Francis J. Kane, Jerome Levine, and Consultant Richard Wittenborn, Ph.D.

Report No. 7 — 54 pages, June 1973 — Single copy $3.00

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety or agitation with depression

Triavil® 4-25

Each tablet contains
4 mg perphenazine and
25 mg amitriptyline HCl

a formulation particularly suited to psychiatric practice when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl

TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and that the full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude, muscle weakness, mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastic distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of tricyclic antidepressant poisoning. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

MSD
MERCK SHARP & DOHME

Mental Illness in Later Life

by Ewald W. Busse, M.D.
Eric Pfeiffer, M.D.

A comprehensive, practical guide for the practicing physician about the emotional problems of the aged patient. Included are pragmatic suggestions for interviewing, diagnosis, treatment, and supportive care, with consideration of social, cultural, and psychological factors. A special *Question-and-Answer* section is a valuable supplement.

"The 12 well written chapters of this book, all by knowledgeable investigators in the field of geriatric mental illness, offer both an overall review of the current status of the field and more detailed information on such specialized topics as the demography of aging, the epidemiology of geriatric mental disorder, diagnostic procedures of the evaluation of brain impairment, social and psychological aspects of mental illness in the aged, insurance coverage for mental illness in later life, organic and functional geriatric mental disorders, physical changes with aging and their relationship to mental functioning, and institutional and ambulatory treatment of the aged mentally ill. The content and approach make the volume appropriate and useful reading both for psychiatrists, who have paid too little attention to the psychiatric problems of the aged, and for social workers, psychologists, nurses, and other personnel who deal with the elderly mentally ill. Pragmatic suggestions are made for interviewing, diagnosis, treatment, and supportive care, and there is adequate emphasis on social, psychologic, and cultural factors. The Question and Answer *section of the book is an especially valuable supplement, especially to readers whose interest is primarily pragmatic."*

Almost any tranquilizer might calm her down...

but at her age, estrogen may be what she really needs.

Throughout a woman's life, periods of low endogenous estrogen production often coincide with heightened levels of anxiety and tension.

In the menopause, many of these symptoms—tension, irritability, headaches, undue fatigue, depression, and insomnia—may respond, at least initially, to minor tranquilizers and antidepressants.

But these symptoms, when caused by declining menopausal estrogen levels, may also be relieved with PREMARIN, which treats the underlying cause by providing adequate estrogen replacement.

And that's something tranquilizers can't do.

In many cases, prolonged use of tranquilizers will not be necessary; patients taking PREMARIN alone often report relief of emotional symptoms due to estrogen deficiency...and an improved sense of well-being.

At the same time, PREMARIN helps relieve concomitant vasomotor symptoms, such as hot flushes and sweats...reverse genital tissue atrophy ...retard postmenopausal osteoporotic changes*.

A simple therapeutic trial is often all that's needed to distinguish between estrogen-related and purely psychogenic symptoms.

PREMARIN.

For what's really missing in the menopause.

*Conjugated Estrogens Tablets have been evaluated as "probably effective" for postmenopausal osteoporosis.

PREMARIN®
(CONJUGATED
ESTROGENS
TABLETS, U.S.P.)
contains natural estrogens
exclusively

even when you start with a tranquilizer, replace estrogen

PREMARIN®

BRAND OF

CONJUGATED ESTROGENS TABLETS, U.S.P.

contains natural estrogens exclusively

BRIEF SUMMARY *(For full prescribing information, see package circular)*
PREMARIN® (CONJUGATED ESTROGENS TABLETS, U.S.P.)

Indications: Based on a review of PREMARIN Tablets by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications for use as follows:
Effective: As replacement therapy for naturally occurring or surgically induced estrogen deficiency states associated with: the climacteric, including the menopausal syndrome and postmenopause; senile vaginitis and kraurosis vulvae, with or without pruritus.
"Probably" effective: For estrogen deficiency-induced osteoporosis, and only when used in conjunction with other important therapeutic measures such as diet, calcium, physiotherapy, and good general health-promoting measures. Final classification of this indication requires further investigation.

Contraindications: Short acting estrogens are contraindicated in patients with (1) markedly impaired liver function, (2) known or suspected carcinoma of the breast, except those cases of progressing disease not amenable to surgery or irradiation occurring in women who are at least 5 years postmenopausal; (3) known or suspected estrogen-dependent neoplasia, such as carcinoma of the endometrium; (4) thromboembolic disorders, thrombophlebitis, cerebral embolism, or in patients with a past history of these conditions; (5) undiagnosed abnormal genital bleeding.
Warnings: Estrogen therapy should not be given to women with recurrent chronic mastitis or abnormal mammograms except, if in the opinion of the physician, it is warranted despite the possibility of aggravation of the mastitis or stimulation of undiagnosed estrogen-dependent neoplasia.
The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, retinal thrombosis, cerebral embolism and pulmonary embolism). If these occur or are suspected, estrogen therapy should be discontinued immediately.
Estrogens may be excreted in the mother's milk and an estrogenic effect upon the infant has been described. The long range effect on the nursing infant cannot be determined at this time.
Hypercalcemia may occur in as many as 15 percent of breast cancer patients with metastases, and this usually indicates progression of bone metastases. This occurrence depends neither on dose nor on immobilization. In the presence of progression of the cancer or hypercalcemia, estrogen administration should be stopped.
A statistically significant association has been reported between maternal ingestion of diethylstilbestrol during pregnancy and the occurrence of vaginal carcinoma in the offspring. This occurred with the use of diethylstilbestrol for the treatment of threatened abortion or high risk pregnancies. Whether or not such an association is applicable to all estrogens is not known at this time. In view of this finding, however, the use of any estrogen in pregnancy is not recommended.
Failure to control abnormal uterine bleeding or unexpected recurrence is an indication for curettage.
Precautions: As with all short acting estrogens, the following precautions should be observed:
A complete pretreatment physical examination should be performed with special reference to pelvic and breast examinations.
To avoid prolonged stimulation of the endometrium and breasts in climacteric or hypogonadal women, estrogens should be administered cyclically (3 week regimen with 1 week rest period—withdrawal bleeding may occur during rest period).
Because of individual variation in endogenous estrogen production, relative overdosage may occur which could cause undesirable effects such as abnormal or excessive uterine bleeding, mastodynia and edema.
Because of salt and water retention associated with estrogenic anabolic activity, estrogens should be used with caution in patients with epilepsy, migraine, asthma, cardiac, or renal disease.
If unexplained or excessive vaginal bleeding should occur, reexamination should be made for organic pathology.
Pre-existing uterine fibromyomata may increase in size while using estrogens; therefore, patients should be examined at regular intervals while receiving estrogenic therapy.
The pathologist should be advised of estrogen therapy when relevant specimens are submitted.
Because of their effects on epiphyseal closure, estrogens should be used judiciously in young patients in whom bone growth is incomplete.
Prolonged high dosages of estrogens will inhibit anterior pituitary functions. This should be borne in mind when treating patients in whom fertility is desired.
The age of the patient constitutes no absolute limiting factor, although treatment with estrogens may mask the onset of the climacteric.
Certain liver and endocrine function tests may be affected by exogenous estrogen administration. If test results are abnormal in a patient taking estrogen, they should be repeated after estrogen has been withdrawn for one cycle.
Adverse Reactions: The following adverse reactions have been reported associated with short acting estrogen administration.

nausea, vomiting, anorexia
gastrointestinal symptoms such as abdominal cramps and bloating
breakthrough bleeding, spotting, unusually heavy withdrawal bleeding (See DOSAGE AND ADMINISTRATION)
breast tenderness and enlargement
reactivation of endometriosis
possible diminution of lactation when given immediately postpartum
loss of libido and gynecomastia in males
edema
aggravation of migraine headaches
change in body weight (increase, decrease)
headache
allergic rash
hepatic cutaneous porphyria becoming manifest

Dosage and Administration: PREMARIN should be administered cyclically (3 weeks of daily estrogen and 1 week off) for all indications except selected cases of carcinoma and prevention of postpartum breast engorgement.
Menopausal Syndrome—1.25 mg. daily, cyclically. Adjust dosage upward or downward according to severity of symptoms and response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.
If the patient has not menstruated within the last two months or more, cyclic administration is started arbitrarily. If the patient is menstruating, cyclic administration is started on day 5 of bleeding. If breakthrough bleeding (bleeding or spotting during estrogen therapy) occurs, increase estrogen dosage as needed to stop bleeding. In the following cycle, employ the dosage level used to stop breakthrough bleeding in the previous cycle. In subsequent cycles, the estrogen dosage is gradually reduced to the lowest level which will maintain the patient symptom-free.
Postmenopause—as a protective measure against estrogen deficiency-induced degenerative changes (e.g. osteoporosis, atrophic vaginitis, kraurosis vulvae)—0.3 mg. to 1.25 mg. daily and cyclically. Adjust dosage to lowest effective level.
Osteoporosis (to retard progression)—usual dosage 1.25 mg. daily and cyclically.
Senile Vaginitis, Kraurosis Vulvae with or without Pruritus—0.3 mg. to 1.25 mg. or more daily, depending upon the tissue response of the individual patient. Administer cyclically.
How Supplied: PREMARIN (Conjugated Estrogens Tablets, U.S.P.) No. 865—Each *purple* tablet contains 2.5 mg., in bottles of 100 and 1,000. No. 866—Each *yellow* tablet contains 1.25 mg., in bottles of 100 and 1,000. Also in unit dose package of 100. No. 867—Each *red* tablet contains 0.625 mg., in bottles of 100 and 1,000. Also in unit dose package of 100. No. 868—Each *green* tablet contains 0.3 mg., in bottles of 100 and 1,000.

Make psychiatric history!

Up here in Maine, we're making some of the most exciting innovations in America.

We're the Augusta Mental Health Institute, Northern New England's outstanding JCAH – accredited hospital. Right now, we need a special breed of Board Eligible or Certified Psychiatrists to join us and help us make history. AMHI is a unitized, participatory management institution that's already a national model for providing services to a rural society.

We've done a lot already and we're not finished yet. We want only flexible, creative types interested in making great professional strides in treatment.

After a 40-hour schedule you can develop a private practice. You'll receive all normal state benefits and an unusually good retirement plan – even possibility of splendid low-cost, on-grounds housing. Salary up to $35,401. Want more details about how you can help write psychiatric history?

Augusta Mental Health Institute

Write or phone: Mr. Roy Ettlinger, Superintendent
Augusta Mental Health Institute
Augusta, Maine 04330. Phone: 207-622-3751

AN EQUAL OPPORTUNITY EMPLOYER

PSYCHIATRISTS

Riverside Center seeks board eligible and board certified Psychiatrists for 225 bed community oriented program. Salaries from $25,640 to $33,512 depending on qualifications.

Also seeking Clinical Services Director. Salary up to $37,751. Prefer board certified Psychiatrist. Would accept well qualified board eligible.

Pleasant, progressive community near Grand Rapids and East Lansing, seat of Michigan State University Medical School. Convenient to wide range of shopping, recreational, and cultural facilities. Outstanding fringe benefits provided by Michigan Civil Service. Send resume to:

Arthur H. Long, Personnel Officer
Riverside Center
777 West Riverside Drive
Ionia, Michigan 48846

AN EQUAL OPPORTUNITY EMPLOYER

Milwaukee Psychiatric Hospital — Intensive, dynamic psychotherapy for adults and adolescents, individually-planned activity therapy.

Adolescent Therapy Unit — Designed for the problems of today's emotionally disturbed youth. Patients attend accredited Kradwell High School on the grounds . . . excellent teaching staff . . . credits are transferrable.

Dewey Center — Acute detoxification and inpatient treatment for persons with dependency on alcohol and other drugs, daily schedules, broad supportive services.

Milwaukee Sanitarium — Custodial services for persons with chronic emotional and geriatric illnesses.

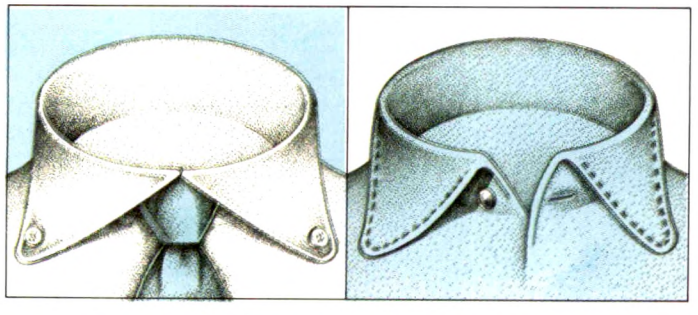
PSYCHIATRISTS

Board eligible and board certified to fashion positions within innovative programs. New medical school affiliation with medical students and residents training within clinical programs. Research and formal teaching opportunities are available. Positions in the Triage-Crisis Intervention, Acute Psychiatry and Intermediate Psychiatry, Out-patient Psychiatry Programs. Salaries from $29,846 to $36,000 based upon qualifications. No discrimination in employment.

Apply to:
Chief of Psychiatry
VA Hospital
Downey, Illinois 60064

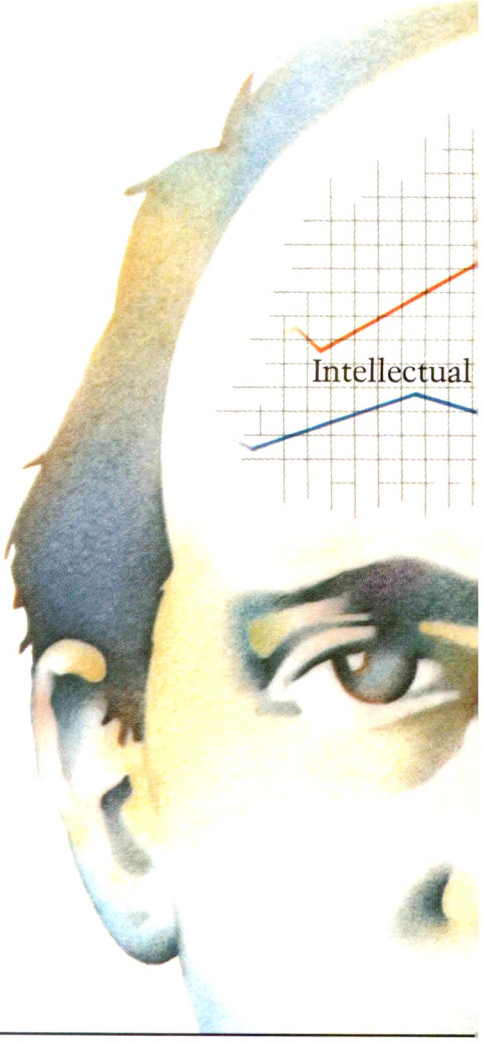
How individual patient variables influenc

It is now well established that certain nondrug factors can affect response to antianxiety medication. Thus, even with agents of proven efficacy, such as Librium (chlordiazepoxide HCl), different patients may exhibit varying degrees of symptomatic relief from excessive anxiety and tension.



1. Rickels K, Lipman RS, Park LC, Covi L, Uhlenhuth EH, Mock JE: *Psychopharmacologia 20*:128-152, 1971
2. Hollister LE: *Ann Intern Med 79*:88-98, July 1973
3. Greenblatt DJ, Shader RI: *Ibid.*, 77: 91-100, July 1972
4. Rickels K, Downing RW, Howard K: *Clin Pharmacol Ther 12*:263-273, Mar-Apr 1971

Apart from the effect of the physician's personality and prescribing attitudes on patient response,[1] there are certain significant patient variables, *e.g.*, personality type, severity and duration of anxiety, socioeconomic status, attitude toward medication and insight into the nature of the condition under treatment.[2-4] Thus, some clinical experience suggests that physically active extroverts, for whom abatement of anxiety may decrease the will to achieve or take action, may respond negatively – resulting in exacerbation of anxiety.[2] On the other hand, more passively anxious individuals with intellectual and esthetic inclinations have been shown t benefit from antianxiety medications.



When medication is indicated in the latter group, many psychiatrists place a high value on the benzodiazepines – of which Librium (chlordiaz-epoxide HCl) was the first in clinical use – for their antianxie effectiveness, broad usefulness and wide margin of safety.[2,3]

Attitude to medication

Socioeconomic status

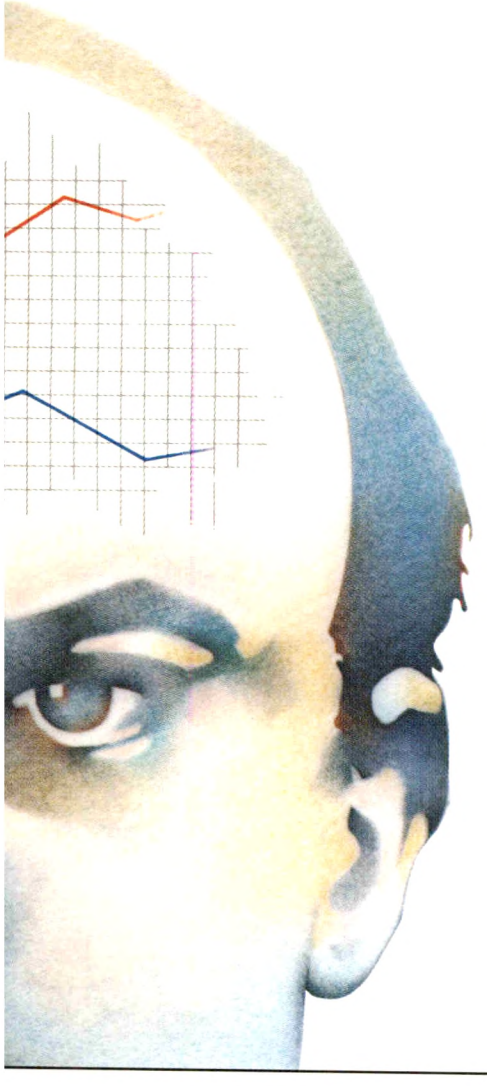
:he effectiveness of antianxiety therapy

Demonstrated predictors of favorable response to Librium (chlordiazepoxide HCl)

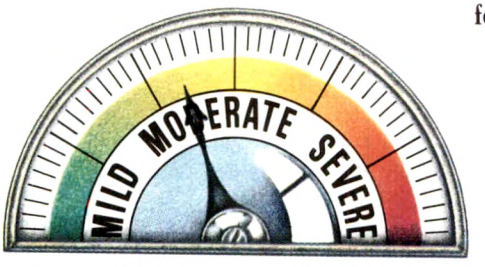
In a double-blind, controlled study[4] of psychoneurotic patients with moderately severe anxiety, 111 patients were treated with Librium in a daily dosage of 30 to 40 mg, and 201 patients received a placebo. Outcome criteria included a global improvement measure after 2 and 4 weeks and the 4-week change score of a 10-item physician questionnaire.

Statistical analysis revealed that the greatest drug-placebo difference in relieving anxiety occurred among patients who were more severely ill, those in a higher socioeconomic class and those whose illness had persisted for at least six months. The more educated patient with high verbal ability, greater insight and an accepting attitude toward combined psychotherapy and drug therapy responded *significantly better* to Librium than to the placebo. On the other hand, patients of lower socioeconomic status, with less insight and greater readiness to accept medication alone as sufficient therapy, tend to show a moderately favorable response to both drug *and* placebo.

For proven effectiveness against excessive, obstructive anxiety

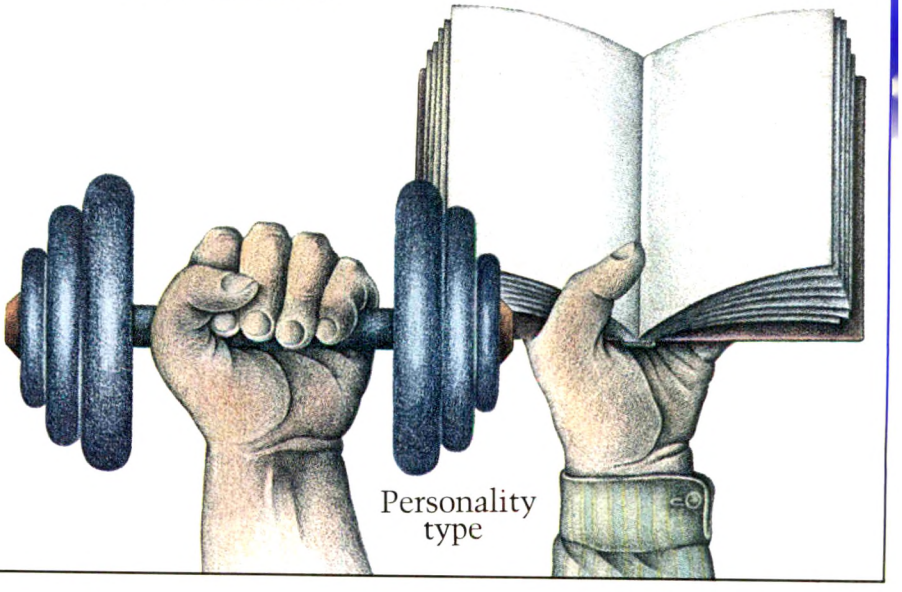


adjunctive



ROCHE **Librium®**

(chlordiazepoxide HCl)

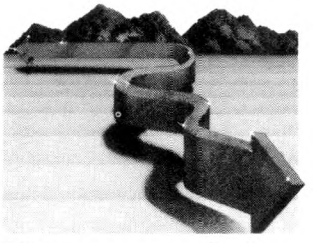


10 mg, 25 mg capsules

Please see following page for summary of product information.

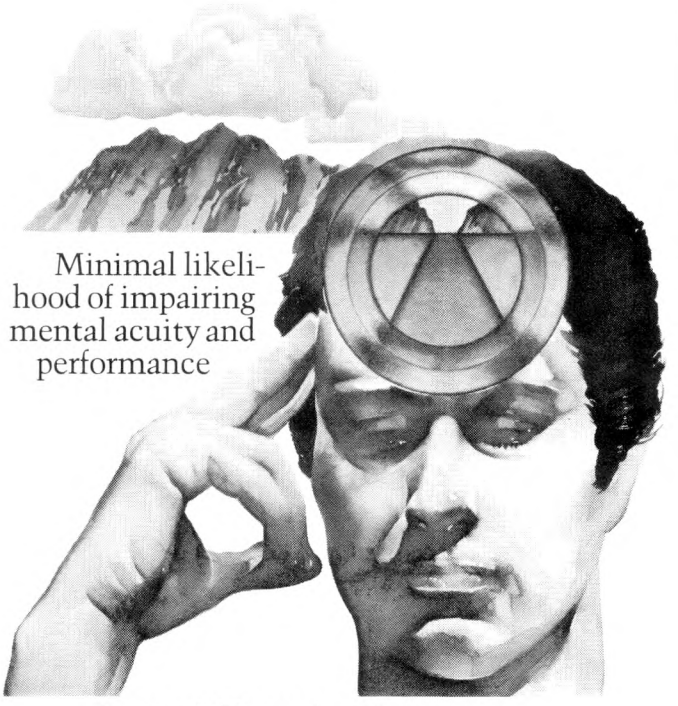
Degree of anxiety

Personality type



Effective adjunct in psychotherapy

Librium® (chlordiazepoxide HCl)



10 mg, 25 mg capsules/up to 100 mg daily in severe anxiety

While drowsiness, ataxia and confusion are the most frequently occurring side effects, physicians should be aware of the possibility of more serious reactions. Before prescribing, please consult complete product information, a summary of which appears below.

When anxiety has been reduced to useful, appropriate levels, Librium should be discontinued.

Wide margin of safety

Minimal likelihood of impairing mental acuity and performance

Dependable antianxiety action

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido – all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral— Adults:* Mild and moderate anxiety and tension, 5 or 10 mg *t.i.d.* or *q.i.d.*; severe states, 20 or 25 mg *t.i.d.* or *q.i.d. Geriatric patients:* 5 mg *b.i.d.* to *q.i.d.* (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) *Capsules*, 5 mg, 10 mg and 25 mg – bottles of 100 and 500; Tel-E-Dose® packages of 100. Libritabs® (chlordiazepoxide) *Tablets*, 5 mg, 10 mg and 25 mg – bottles of 100 and 500. With respect to clinical activity, capsules and tablets are indistinguishable.

Q QUESTION:

WHAT TRICYCLIC ANTIDEPRESSANT IS AVAILABLE AS AN ORAL CONCENTRATE?

A ANSWER: SINEQUAN® DOXEPIN HCl ORAL CONCENTRATE

10 mg./ml., 120-ml. (4-oz.) bottles

- ☐ Effective in the treatment of clinical depression/anxiety
- ☐ Eliminates potential for "cheeking" medication
- ☐ Colorless, tasteless following dilution
- ☐ Contains no alcohol or sugar
- ☐ Easily mixed with water or juices

BRIEF SUMMARY

Sinequan® (doxepin HCl) **Capsules/Oral Concentrate**

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* This drug has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: Usage in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan, however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan does exert a significant blocking effect. In addition, Sinequan was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). Sinequan (doxepin HCl) 25 mg. and 50 mg. also available in bottles of 5000. Sinequan Oral Concentrate (10 mg./ml.) is available in 120 ml. bottles with an accompanying dropper calibrated at 5 mg., 10 mg., 15 mg., 20 mg., and 25 mg.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630.
Stelazine® trademark licensed by SmithKline Corporation.

patients most in need of phenothiazines are often least able to cope with their side effects

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.

Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Tardive dyskinesia may appear in some patients on long-term therapy with phenothiazines and related agents, or may occur after therapy with these drugs has been discontinued; antiparkinsonism agents usually do not alleviate symptoms of tardive dyskinesia, and in some instances may aggravate or unmask such symptoms.

May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/ml

COGENTIN®
(Benztropine Mesylate | MSD)
helps alleviate most phenothiazine-induced extrapyramidal symptoms

In a recent study of 71 patients treated with antipsychotics, COGENTIN, administered in a double-blind manner in various dosage schedules, was found to be highly successful in relieving phenothiazine-induced extrapyramidal symptoms.[1] Patients experienced relief of such symptoms as facial and hand tremors, muscle weakness, sensations of psychic and motor excitation, and akathisia.

1. Neu C, Dimascio A, Demirgian E: Antiparkinson medication in the treatment of extrapyramidal side effects: single or multiple daily doses? Curr Ther Res *14*:246, May 1972.

impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.

Adverse Reactions: Adverse reactions may be anticholinergic or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Note: Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Patients with a poor mental outlook are usually poor candidates for therapy. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. When benztropine mesylate is used with levodopa the usual dose of each may need to be reduced. Certain extrapyramidal disorders that develop slowly, such as tardive dyskinesia, usually do not respond to the drug.

How Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000; Injection, containing 1.0 mg benztropine mesylate and 9.0 sodium chloride per ml, in 2-ml ampuls.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., INC., West Point, Pa. 19486

MSD
MERCK SHARP & DOHME

addendum

Facts about dosage schedules of COGENTIN (Benztropine Mesylate | MSD) in treating drug-induced extrapyramidal symptoms

In treating extrapyramidal symptoms due to central nervous system drugs, such as reserpine and phenothiazines, the recommended dosage of COGENTIN is 1 to 4 mg once or twice a day orally or parenterally. The tablet form should be used when patients are able to take oral medication.

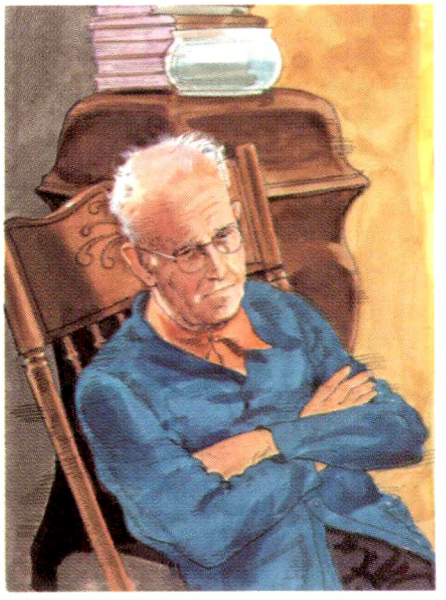
When extrapyramidal symptoms develop soon after initiation of phenothiazine treatment, they are likely to be transient. One to 2 mg COGENTIN orally two or three times a day usually provides relief within one or two days. After one or two weeks, COGENTIN should be withdrawn to determine the continued need for it. If symptoms recur, COGENTIN can be reinstituted.

Certain extrapyramidal disorders that develop slowly, such as tardive dyskinesia, usually do not respond to COGENTIN.

For more detailed information, see full prescribing information.

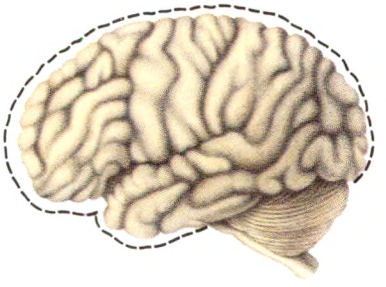
Adapting to age: time and the mind

Aging successfully: is the goal just survival?



Popular belief would have it that "aging" and "existing" are the same, both marked by deteriorated ability—physical and mental. But is successful aging just existing?

Or is it making the most of one's abilities?



More than just surviving the changes and obstacles of old age, successful aging is *adapting* to the changes and *overcoming* the obstacles. Consider the very fortunate aging individuals who continue active, productive, even socially significant lives. Picasso, painting and sculpting until his death at the age of 91. Stokowski still conducting at 92. Margaret Mead, an active author and anthropologist at 73. Consider, too, those who lack prominence and popular acclaim, but still lead personally satisfying lives. Thus adding meaning to their prolonged existence by following interests and abilities.

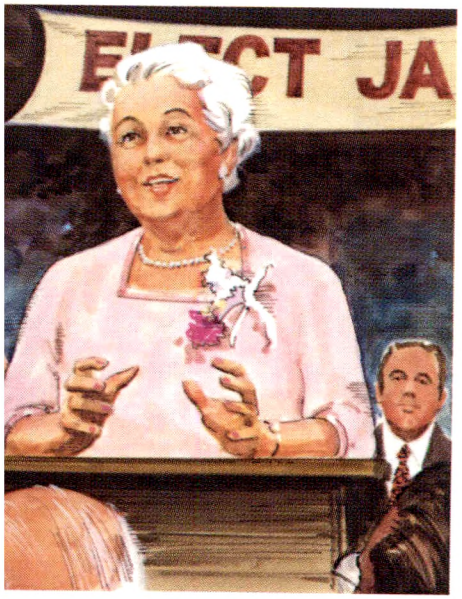
How then, can some age so successfully, others less so, and still others merely survive? One reason: individual differences. Not only in abilities, but in opportunities and situations that can either nurture or suffocate ability.

Aging doesn't have to mean ailing bodies and failing minds. True, the cell loss of old age extends to the brain. But

the loss of brain cells doesn't invariably lead to loss of intelligence and alertness. For,

Although the decrease in brain volume is well known,

enormous reserves of cerebral cells help compensate for loss with age. Disease and injury, more than advancing age, actually lessen cerebral capacity.



And lack of use contributes to the decline; mental and physical functions that are utilized tend to persist and those not utilized tend to disappear. So, if used, the mind often can remain alert. And, in fact,

Some now believe that intellectual decline can be minimal.

One theory isolates two basic types of intelligence: "fluid" and "crystallized." Both increase into adolescence, but fluid intelligence, formless and independent of education, begins to decline during the twenties. Crystallized intelligence—experience refined through education—continues to grow, and does not decline or even level off during old age. So, according to this theory, total intelligence changes qualitatively. Quantitatively, it remains relatively constant.

But we still see senility and seeming mental decline, sometimes caused by

injury to the brain from accident or a disease like cerebral arteriosclerosis. In some cases, the reason may be personality frustration even more than actual brain deterioration: a decline in *performance* generated by severe stress more than a decline in *cognitive ability.* Clinically significant anxiety, alone or associated with underlying organic disease, is common in the elderly, and can cripple the aged mind, and interfere with the adaptive process. But

When such anxiety is controlled the elderly patient may become more responsive to personal interests and social activities.

To therapy and counselling. To adapting to the changes of age.

If antianxiety therapy adjunctive to your counsel and reassurance is desirable, consider Serax (oxazepam). Serax has been found valuable, particularly in the older patient, in the management and control of clinically significant anxiety, tension, agitation and irritability.

Special care must of course be taken in prescribing antianxiety agents for elderly patients, especially where cardiac complications might ensue from a drop in blood pressure. And careful attention must be paid to dosage recommendations and follow-up observation.

More than eight years of clinical experience have shown Serax to be especially useful in many geriatric patients. Its dosage flexibility* generally permits adjustment to individual patient needs, making Serax a logical choice in the management of clinically significant anxiety in the elderly patient.

In Brief:

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease. Anxiety associated with depression is also responsive to oxazepam therapy. This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients. Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

*See package circular for full prescribing information.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: Use in Pregnancy: Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance. Not indicated in children under 6 years; absolute dosage for 6- to 12-year olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

DEPENDABILITY

For effective management of psychotic symptoms

- unsurpassed clinical experience
- widely researched and documented
- 18 dosage forms and strengths for maximum flexibility

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol.

©1967, 1968, 1969 SmithKline Corporation

May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100 and Single Unit Packages of 100. Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50 and Single Unit Packages of 100. Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate, 30 mg./ml. and 100 mg./ml.

Smith Kline & French Laboratories
Division of SmithKline Corporation, Philadelphia

THORAZINE®

brand of **CHLORPROMAZINE** Tablets: 50 mg. of the HCl

That's no surprise.

CHARLES C THOMAS • PUBLISHER

THE MALPRACTICE OF PSYCHIATRISTS: Malpractice in Psychoanalysis, Psychotherapy and Psychiatry *by* **Donald J. Dawidoff,** *Practicing Attorney, New York.* The author describes possible areas of malpractice by psychiatrists and examines both the nature of and remedy for malpractice in the verbal therapies of psychoanalysis and psychotherapy. The difficulties awaiting application of the canons of malpractice to such therapy are explored at length. Also. canons of malpractice to such therapy are explored at length. Also, the specialized legal theories of breach of fiduciary duty, undue influence and words negligently spoken are applied to psychotherapy and psychoanalysis. A sampling of psychiatric literature is set forth to indicate the doctrinal recognition of concepts described. *'73, 184 pp., $9.75*

EPIDEMIOLOGICAL PSYCHIATRY *by* **Brian Cooper,** *Univ. of London, London, England, and* **H. G. Morgan,** *Univ. of Bristol, Bristol, England. Foreword by* **Michael Shepherd.** Written primarily for psychiatrists in training or in clinical practice, this book demonstrates that the improved perspective gained through the epidemiological approach can answer many questions regarding the nature and treatment of mental illness. A review of the principal ways in which epidemiological research has contributed to current knowledge of the distribution, natural history and causes of psychiatric morbidity is presented. Possible future developments are assessed, particularly in relation to the impact on epidemiology of new clinical laboratory and statistical research techniques. *'73, 232 pp., 13 il., 40 tables, $12.50*

A PRACTICAL HANDBOOK OF PSYCHIATRY *edited by* **Joseph R. Novello,** *University of Michigan, Ann Arbor, Michigan. (17 Contributors)* Part I of this handy text provides an immediate source of sound, practical information for use on the "firing line" of everyday work by psychiatrists, other medical practitioners and medical students. Part II presents reading lists, available psychiatric journals and training opportunities in some of the subspecialties. A final section is a concise compilation of addresses of professional organizations and institutions related to psychiatry. This is a handbook containing a maximum of clinically useful information with a minimum of verbiage in a brisk and readable format. *'74, 648 pp., 10 il., 47 tables, $16.75*

INDECENT EXPOSURE *by* **John M. Macdonald,** *Univ. of Colorado, Denver. Chapter by* **N. K. Rickles.** This book is based not only upon a study of offenders and their victims, but also upon analysis of the Denver Police Department records on 200 consecutive reports of indecent exposure. Psychological aspects of exhibitionism receive particular attention and one chapter considers the mothers of exhibitionists and their role in promoting this unusual behavior. Police raids on nudist camps, criminal investigation of indecent exposure, legal aspects of this problem, sexual psychopath laws and the punishment of offenders are reviewed. A concluding chapter on treatment includes recent advances in behavior therapy. *'73, 180 pp., 10 tables, $7.95*

A PSYCHIATRIC STUDY OF MYTHS AND FAIRY TALES: Their Origin, Meaning and Usefulness. An Enlarged and Thoroughly Revised Second Edition of A Psychiatric Study of Fairy Tales (2nd Ed.) *by* **Julius E. Heuscher,** *Stanford Univ., Stanford, California.* The images of myths and fairy tales remain familiar to the child within us, to the artist within our soul. Thus they may, even today, help the adult's quest for harmony and wholeness that is threatened by onesidely intellectual and sensory orientations. These images may also be introduced beneficially in psychotherapy. The adult who develops a fine awareness for their potential depth and power can communicate to the child the content of this lost and yet always young language. *'73, 448 pp., 11 il., 14.95*

LIFE STRESS AND ILLNESS *edited by* **E. K. Eric Gunderson,** *Univ. of California, San Diego, and* **Richard Rahe,** *Univ of California, Los Angeles. (19 Contributors)* This book is based upon contributions to the NATO-sponsored Symposium on "Life Stress and Illness" held in Beito, Norway. It critically examines relationships between stressful life events and various types of illness. A major emphasis in the book is the development of quantitative techniques for the measurement of life stress and the scaling of specific life events which have special significance for the onset of disease. The physiological and psychological effects of severe stress, such as prison confinement, are described as well as the effects of milder everyday stress. *'74, 276 pp., 25 il., 27 tables, $19.50*

OCCUPATIONAL STRESS *edited by* **Alan McLean,** *New York Hospital, White Plains.* This book is the first to present widely held concepts of occupational stress in a single volume. The purpose of the Occupational Mental Health Conference at the Center for Occupational Mental Health was to bring together representatives from the many concerned disciplines to present their viewpoints so that a picture of current thinking could be obtained and the various definitions of the term understood. Based upon this conference, this book presents theoretical concepts, research results and various specific suggestions for coping with stress-related problems. Psychiatric, psychoanalytic and psychophysiological considerations are discussed as stemming from role theory. *'74, 128 pp., 21 il., 9 tables, $9.75*

A NEUROPHYSIOLOGICAL MODEL OF EMOTIONAL AND INTENTIONAL BEHAVIOR *by* **John L. Weil,** *Harvard Medical School, Boston.* Researchers, theoreticians and clinicians will be interested in the presentation of this model of behavior constructed in answer to the current need for establishing lines of communication between the fields of neurophysiology, experimental psychology and clinical psychiatry. The clarity of the colored illustrations, diagrams, flow charts and tables will be welcomed by students in medicine and physiological psychology as well as by the reader who is seeking to understand central nervous system processes pertaining to the interaction of emotion, cognition and intention. *'74, 204 pp. (7 x 10), 50 il. (24 in full color), 28 tables, $15.75*

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

THE AMERICAN PSYCHIATRIC ASSOCIATION

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

MONTEFIORE HOSPITAL AND MEDICAL CENTER

The Department of Psychiatry

Department of Psychiatry, Albert Einstein College of Medicine

offers

FELLOWSHIPS

in

A POST-DOCTORAL RESEARCH TRAINING PROGRAM

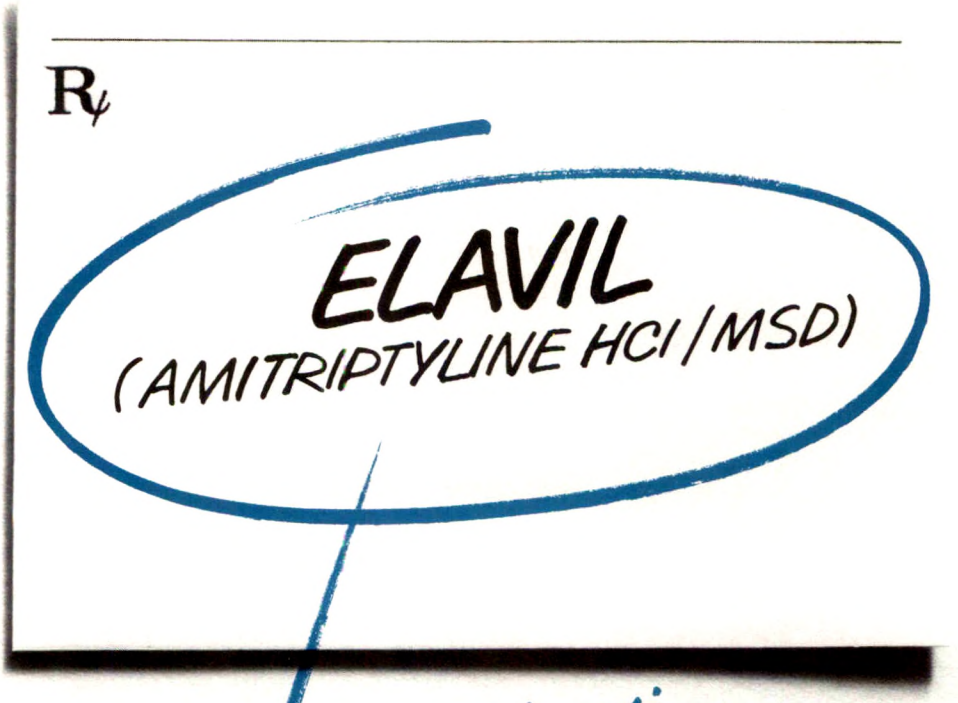
Fellowship positions are available through N.I.M.H.-supported programs that provide basic preparation for research in areas relevant to mental health, the brain and behavior. The program is available to psychiatrists who have completed training and to individuals who have completed the requirements for a doctorate degree.

Emphasis is on acquiring proficiency in the fundamental principles of research strategy, methodology and techniques currently employed in laboratory and clinical studies in psychiatry. The traineeships stress active participation in research work under the supervision of faculty preceptors, supplemented by a curriculum of seminars and workshops.

Appointments are full-time and may extend to two years.

For details, write to:

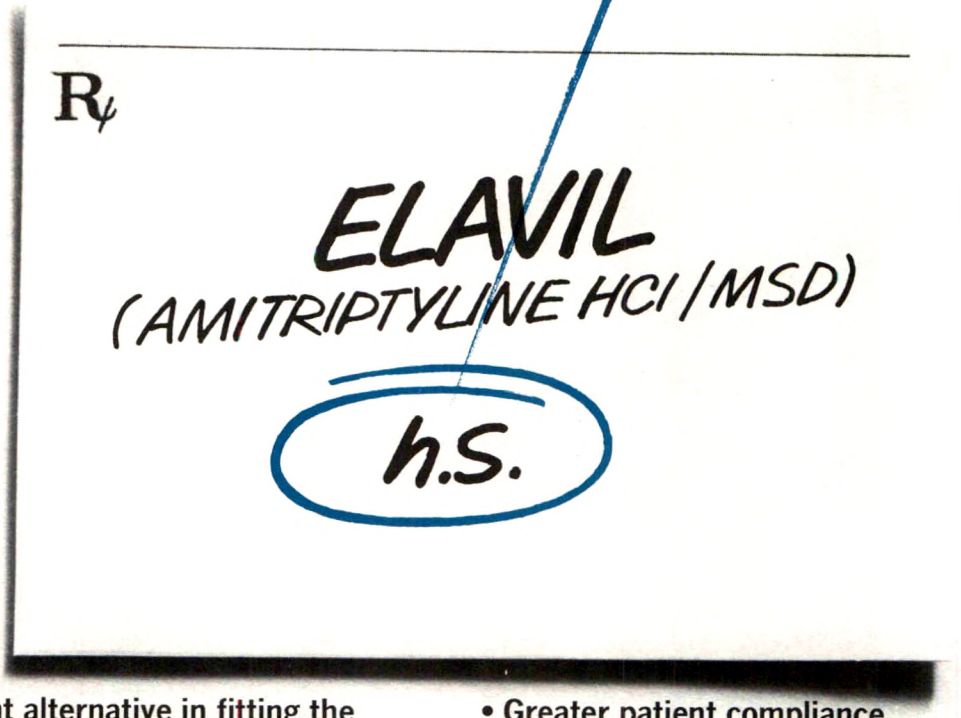
Herbert Weiner, M.D., Chairman
Department of Psychiatry
Montefiore Hospital and Medical Center
111 East 210th Street
Bronx, New York 10467



The April 1975 issue of

The American Journal of Psychiatry

will feature



- Lee Gurel on
  Psychiatric Residency Training Programs

In the treatment of clinically significant depression...

For highly effective symptomatic relief... the reason to prescribe it

Now added dosage versatility...

- **An important alternative in fitting the medication to the patient's needs**

  Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. Of course, ELAVIL may be administered two, three, or four times as well as once a day. This dosage versatility allows prescribing precisely for the patient's needs.

- **Once-a-day dosage schedule for adult outpatients**

  Therapy should be initiated with 50 mg to 100 mg at bedtime. This may be increased by 25 or 50 mg added to the bedtime dose as necessary to a maximum daily dose of 150 mg. The usual maintenance dose is 50 to 100 mg a day given at bedtime, though in some patients, 40 mg per day is sufficient.

- **Greater patient compliance**

  The simplicity of once-a-day dosage at bedtime makes it easier for patients to adhere to a regimen—an especially important consideration in depressed patients whose self-motivation may be at a low ebb.

Should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

once a day at bedtime

Please see addendum on following page for other details of dosage and administration including divided daily doses, dosage in hospitalized patients, and dosage in elderly and adolescent patients.

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

added dosage versatility in clinically significant depression

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: ***Note:*** Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. ***Cardiovascular:*** Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. ***CNS and Neuromuscular:*** Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. ***Anticholinergic:*** Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. ***Allergic:*** Skin rash, urticaria, photosensitization, edema of face and tongue. ***Hematologic:*** Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. ***Gastrointestinal:*** Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. ***Endocrine:*** Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. ***Other:*** Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. ***Withdrawal Symptoms:*** Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of tricyclic antidepressant poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

addendum

MSD MERCK SHARP & DOHME

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for initial therapy in adult outpatients. Starting dosage is usually 75 mg daily in divided doses or 50 to 100 mg once a day at bedtime. If necessary, this dosage may be increased gradually to a total of 150 mg a day. When doses are divided, dosage increases are made preferably in the late afternoon or at bedtime. A sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be advantageous whenever higher dosages are required, or when the single daily dose is given at bedtime. The 50-mg tablet may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

When you see anxiety-look for depression
NORPRAMIN®
(desipramine hydrochloride)

when depression is primary

NORPRAMIN®
(desipramine hydrochloride)

HELPS PROVIDE EARLY CONTROL OF DEPRESSIVE SYMPTOMS...

Anxiety is an invidious symptom. It feeds upon sickness, gnaws, grows and invades every cranny of psychic pathology adding intensity to torment. Anxiety as a symptom secondary to depression may be so dominant that it obscures the primary diagnosis. It may suggest treatment with tranquilizers which often help. But as the vampire of legend had to have a laurel stake driven through its heart to truly die, so anxiety secondary to depression will not cease to nibble and bite until an antidepressant eradicates the primary illness—and symptomatic anxiety starves.

IN BRIEF:

Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. If possible, dispense in child-resistant containers. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of phychosis in schizophrenic patients. Use cautiously with anticholinergic or sympathomimetic drugs. Response to alcoholic beverages may be exaggerated. In the concurrent administration of ECT and antidepressant drugs one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is neutropenia.

Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially in the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of phychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.

Milwaukee, Wisconsin 53201

It always happens so fast.

And, this time, you're right. It did happen to "the other guy."

You know: The guy who wouldn't hurt a fly, turn down a friendly drink—or take a cab home instead of driving. A nice guy who'd now and then smoke in bed, maybe swim out a little too far, sometimes hurry a little down the stairs.

We know you knew him. And that you'll miss him.

We just don't want you to join him.

"Oops" is a pitiful epitaph.

National Safety Council

If you don't like thinking about safety, think where you'd be without it.

A reminder from the National Safety Council. A non-profit, non-governmental public service organization. Our only goal is a safer America.

Akineton® hydrochloride (biperiden hydrochloride) Tablets/Ampules

Contraindications: The only known contraindication is sensitivity to Akineton hydrochloride.

Warnings: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients.

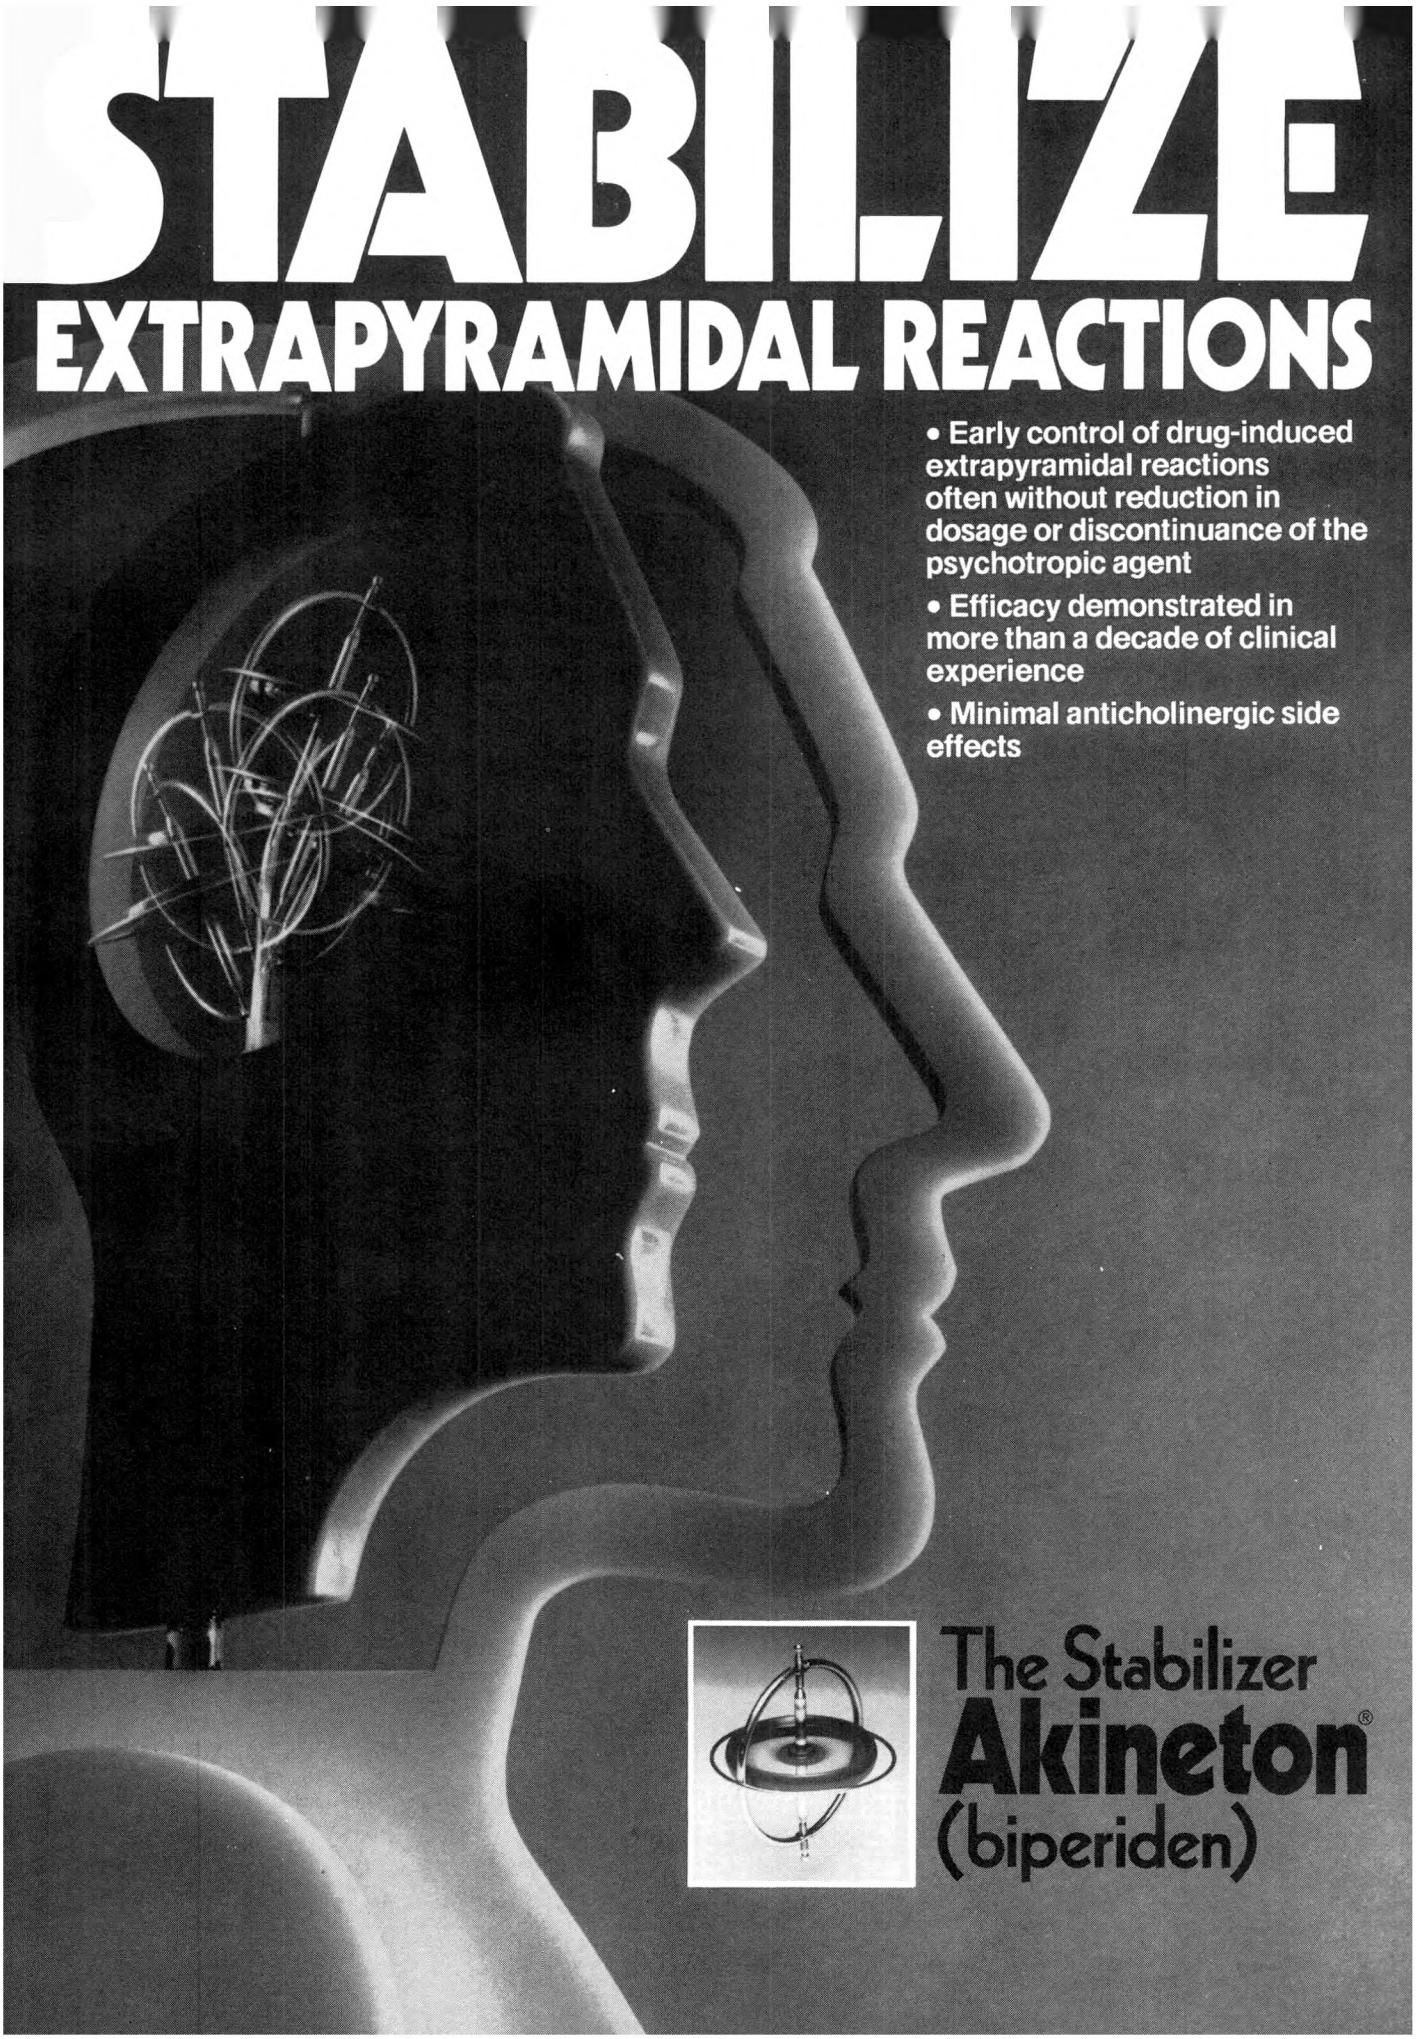
Precautions: Caution should be observed in patients with manifest glaucoma, though no prohibitive rise in intraocular pressure has been noted following either oral or parenteral administration. Patients with prostatism or cardiac arrhythmia should be given this drug with caution. Occasionally, drowsiness may occur.

Adverse reactions: Adverse reactions encountered are primarily dry mouth and blurred vision. These side effects are usually slight and can be overcome by judicious reduction of dosage. If gastric irritation occurs, it can be avoided by administering during or after meals.

Dosage and Administration: Doses required to achieve therapeutic goal are variable and must be individually and gradually adjusted.

Parkinson's disease: 1 tablet, 2 mg. three or four times daily.

Drug-induced extrapyramidal disorders: 1 tablet, 2 mg. one to three times daily.



How Supplied:

Akineton hydrochloride tablets, 2 mg. each, bisected—bottles of 100 and 1000.

Akineton lactate ampules, 1 ml. each containing 5 mg./ml. in an aqueous 1.4 percent sodium lactate solution. No added preservative. Boxes of 10.

Additional literature available upon request.

• Minimal anticholinergic side effects
The Stabilizer
Akineton®
(biperiden)

May be the start of a better life for the epilepti

About nine out of ten epileptics suffer their first seizure in childhood.[1] Certain physical and psychic postseizure evidence—a badly bitten tongue, broken or dropped objects, amnesia, exhaustion—may suggest grand mal. Once the diagnosis of epilepsy has been established, *MYSOLINE (primidone) may mean the start of a seizure-free life.*

Early therapy for control of grand mal, focal and psychomotor epilepsy. Used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. Based years of clinical success, MYSOLINE has ear the reputation of being an *excellent* drug for trol of grand mal epilepsy.[2-4] But its usefulnes not confined to this type alone: MYSOLINE proved to be valuable for control of psychomoto and focal epilepsy[5] as well.

Improves response to concomita therapy. When other anticonvulsants prove be inadequate, adding MYSOLINE to the regin can improve seizure control in grand mal and

chomotor epilepsy. A double-blind comparative study[6] shows that the combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.

Effective changeover therapy. Unsatisfactory performance or important side effects may force discontinuation of the patient's existing anticonvulsant therapy. For more effective control, MYSOLINE may be added to the patient's present regimen, then gradually substituted for the original medication. The changeover to MYSOLINE is frequently warranted when grand mal is refractory to phenobarbital, with or without diphenylhydantoin.[7]

Ayerst®

AYERST LABORATORIES
New York, N.Y. 10017

Mysoline® (primidone) May be the start of a better life for the epileptic

initial and maintenance therapy for grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY

(For full prescribing information, see package circular.)

MYSOLINE® Brand of **PRIMIDONE**

Anticonvulsant

INDICATIONS: MYSOLINE, either alone or in combination, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

Use in pregnancy: The effect of primidone on the human fetus has not been studied, and the benefit of administration of any drug during pregnancy must be weighed against any possible effect on the fetus.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking MYSOLINE and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

In nursing mothers: There is evidence that in mothers treated with MYSOLINE, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. On rare occasion, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE (primidone) and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 mg. Increments of 250 mg. are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 Gm. A typical dosage schedule for the introduction of MYSOLINE is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg., with gradual weekly increases of 125 mg. a day, to a daily total usually between 500 mg. and 750 mg.

In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances: for initiation of combination therapy; during "transfer" therapy; for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.).

HOW SUPPLIED: MYSOLINE *Tablets*—No. 430—Each tablet contains 250 mg. of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg. of primidone (scored), in bottles of 100 and 500. MYSOLINE *Suspension*—No. 3850—Each 5 cc. (teaspoonful) contains 250 mg. of primidone, in bottles of 8 fluidounces.

THE FREE PRESS
A DIVISION OF MACMILLAN PUBLISHING CO., INC.
100D Brown Street, Riverside, New Jersey 08075

"Insomnia often occurs when a patient is troubled by a problem for which he is not prepared."

Passing on a valid point:
a sense of continuity from one generation of psychiatrists to another.

Insomnia is a problem for which NOLUDAR® 300 (methyprylon) C III is prepared

Effectiveness. A single capsule of Noludar 300 generally provides an uninterrupted night's sleep of from 5 to 8 hours duration. Sleep is usually induced within 45 minutes.

Safety. While Noludar 300 is a Schedule III controlled medication, it is not a barbiturate or a methaqualone. Administer with caution to individuals known to be addiction-prone or those whose history suggests they may increase the dosage on their own initiative.

Reliability. Noludar is a reliable hypnotic in use for over 19 years. It can help the insomniac patient sleep and wake refreshed to meet the new day, usually with little or no morning-after "hang-over." At recommended dosages (one capsule before retiring), paradoxical excitation has been rare.

Before prescribing, please consult Complete Product Information, a summary of which follows:

INDICATION: As a hypnotic for relief of insomnia of varied etiology.

CONTRAINDICATIONS: Patients with known hypersensitivity to the drug.

WARNINGS: Caution patients about combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness, such as operating machinery or driving a motor vehicle shortly after ingesting the drug.

Physical and Psychological Dependence: Physical and psychological dependence have been reported infrequently. Withdrawal symptoms, when they occur, tend to resemble those associated with withdrawal of barbiturates and should be treated in a similar fashion. Use caution in administering to individuals known to be addiction-prone or those whose history suggests they may increase the dosage on their own initiative. Repeat prescriptions should be limited without adequate medical supervision.

Usage in Pregnancy: Weigh potential benefits in pregnancy, during lactation, or in women of childbearing age against possible hazards to mother and child.

Usage in Children: Not recommended in children under 3 months of age.

PRECAUTIONS: Total daily intake should not exceed 400 mg, as greater amounts do not significantly increase hypnotic benefits. Observe usual precautions in hepatic or renal disorders. Perform periodic blood counts if used repeatedly or over prolonged periods.

ADVERSE REACTIONS: At recommended dosages, there have been rare occurrences of morning drowsiness, dizziness, mild to moderate gastric upset (including diarrhea, esophagitis, nausea and vomiting), headache, paradoxical excitation and skin rash. There have been a very few, isolated reports of neutropenia and thrombocytopenia; however, the evidence does not establish that these reactions are related to the drug.

SUPPLIED: *Capsules* containing 300 mg methyprylon. *Tablets* containing 200 mg or 50 mg methyprylon.

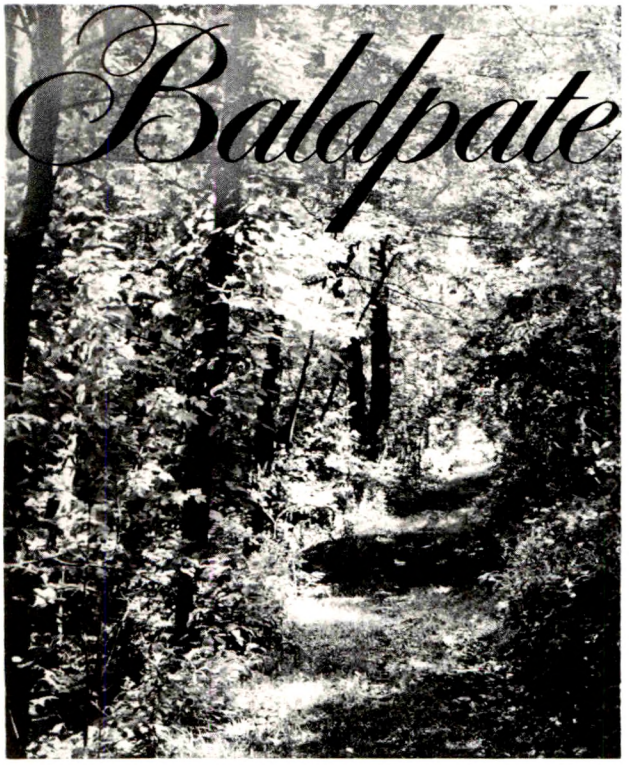
Dear Doctor:

What happens to your patient when he/she has completed their period of intensive psychiatric hospitalization?



Do you feel that he is ready to assume the responsibilities of daily living in an unstructured environment? Or do you feel certain that a period of time with supervision would ensure a more stable adjustment to family life?

There is just such a facility.

1. Nursing supervision is available.
2. Recreational therapy is creative and challenging.
3. Dining is superb — Therapeutic diets available.
4. Companionship.
5. Charming decor.

Q QUESTION:

WHAT TRICYCLIC ANTIDEPRESSANT IS AVAILABLE AS AN ORAL CONCENTRATE?

A ANSWER: SINEQUAN® DOXEPIN HCl ORAL CONCENTRATE

10 mg./ml., 120-ml. (4-oz.) bottles

- ☐ Effective in the treatment of clinical depression/anxiety
- ☐ Eliminates potential for "cheeking" medication
- ☐ Colorless, tasteless following dilution
- ☐ Contains no alcohol or sugar
- ☐ Easily mixed with water or juices

BRIEF SUMMARY

Sinequan® (doxepin HCl) **Capsules/Oral Concentrate**

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* This drug has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: Usage in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan, however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan does exert a significant blocking effect. In addition, Sinequan was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). Sinequan (doxepin HCl) 25 mg. and 50 mg. also available in bottles of 5000. Sinequan Oral Concentrate (10 mg./ml.) is available in 120 ml. bottles with an accompanying dropper calibrated at 5 mg., 10 mg., 15 mg., 20 mg., and 25 mg.

EXPERIMENTAL APPROACHES TO PSYCHOPATHOLOGY

edited by MITCHELL L. KIETZMAN, SAMUEL SUTTON and JOSEPH ZUBIN

A Volume in the
PERSONALITY AND PSYCHOPATHOLOGY
Series

This volume contains empirical and theoretical chapters both by active researchers in experimental psychopathology, and by researchers in other fields relevant to experimental psychopathology.

PARTIAL CONTENTS: Arousal: *R. Hernández-Péon,* Some Neurophysiological Models in Psychopathology. *M. H. Lader,* Arousal Measures and the Classification of Affective Disorders. Attention: *J. Zubin,* Problem of Attention in Schizophrenia. *G. Horn,* Attention and the Orientation Response. Learning: *K. Salzinger,* Behavior Theory Models of Abnormal Behavior. *N. E. Miller,* Some Clinical Implications of Visceral Learning. Methodological Issues: *H. E. Lehman,* Types and Characteristics of Objective Measures of Psychopathology. *H. E. King,* Psychomotor Correlates of Behavior Disorder.

Announcing a New Serial Publication

PROGRESS IN BEHAVIOR MODIFICATION

edited by MICHEL HERSEN, RICHARD M. EISLER and PETER M. MILLER

This new serial publication will publish invited original critical surveys and evaluations of new developments in methods, clinical practice, theory, and research. It will cover a wide range of problem areas involving several disciplines, including psychology, psychiatry, social work, education, and remedial education.

Topics to be covered include: treatment modalities; application in clinical practice; modification of classroom behavior; description of animal analogues; social influences on behavior; measurement and modification of addictive behaviors; control of psychophysiological processes; use of drugs in behavioral approaches; remedial education; and research methodology.

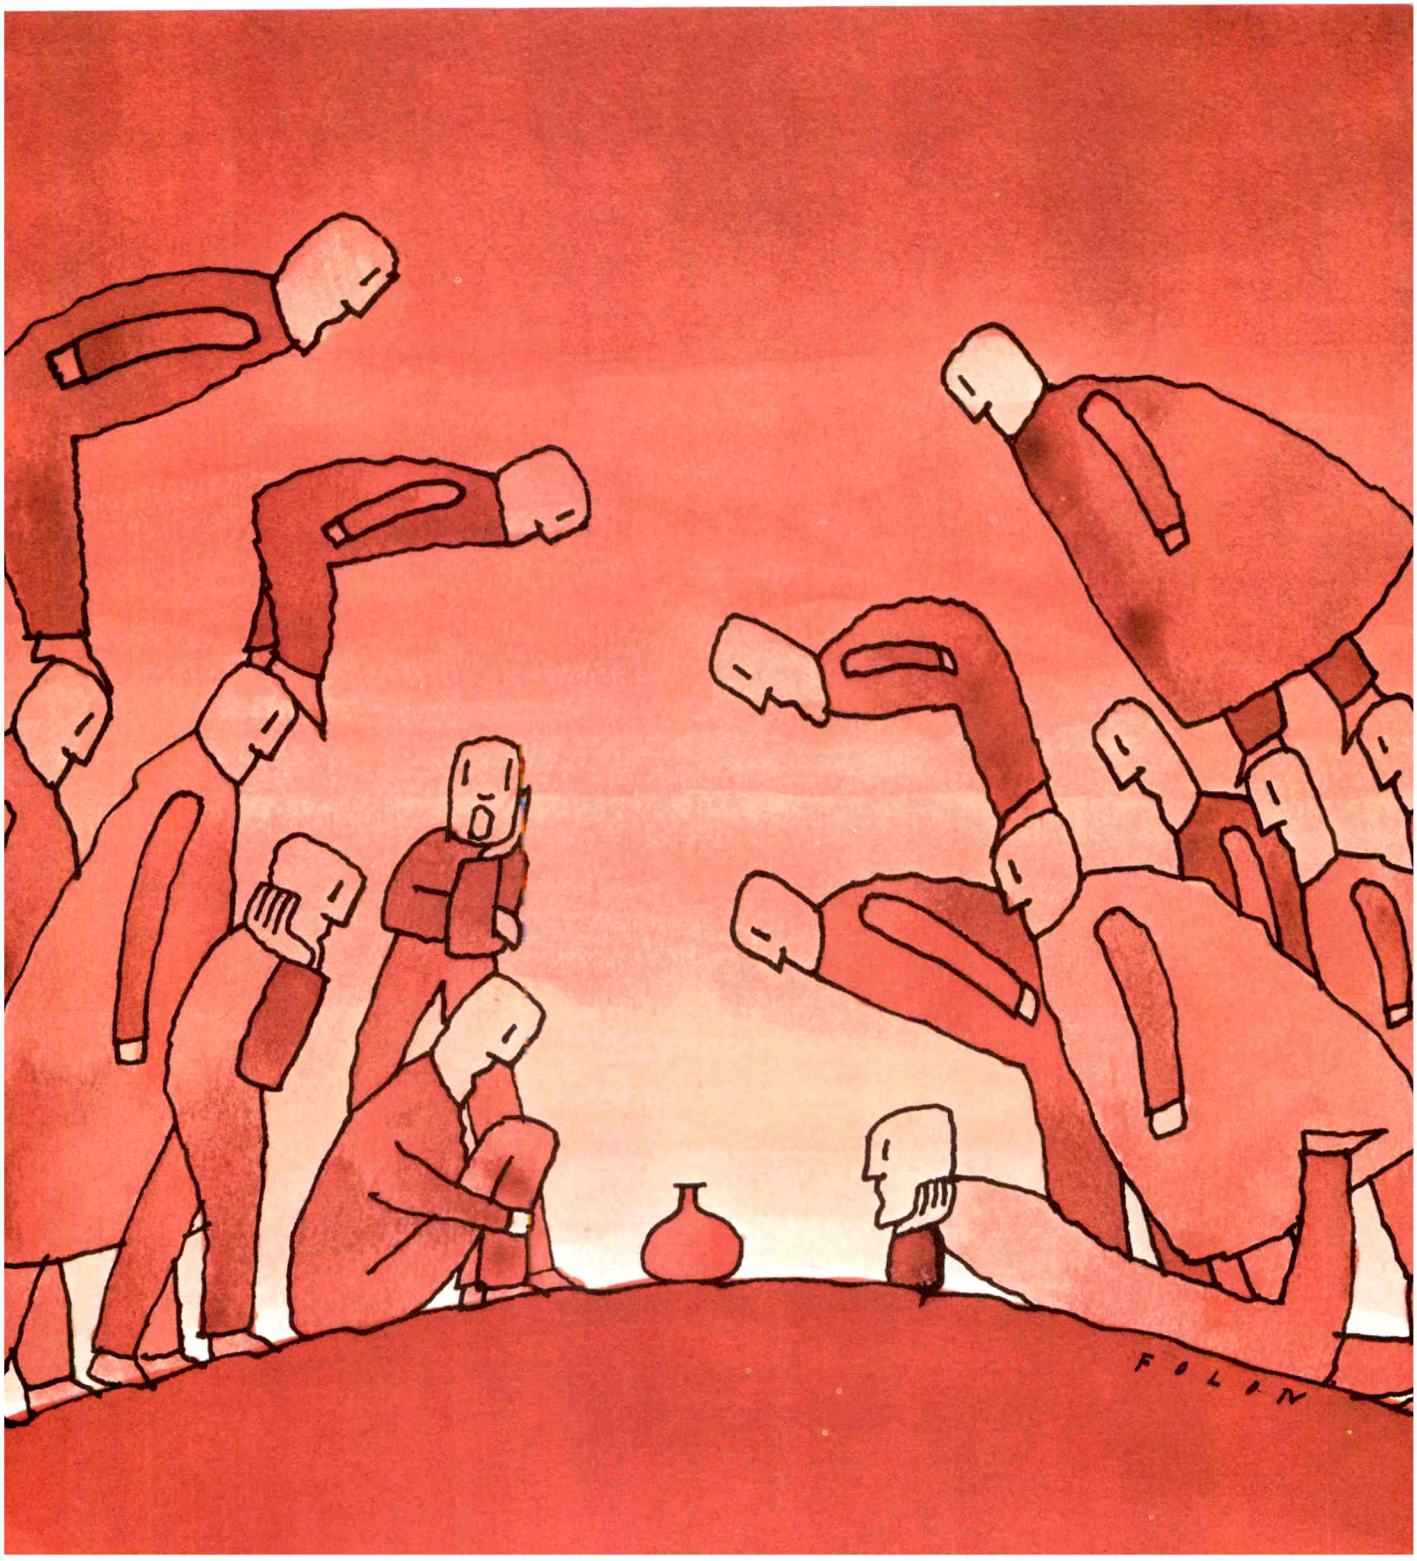
VOLUME 1/1975, about 400 pp., in preparation

APPLICATIONS OF BEHAVIOR MODIFICATION

edited by TRAVIS THOMPSON and WILLIAM S. DOCKENS, III

This volume is perhaps the largest collection of original contributions by significant investigators in the field to appear to date, and covers an unusually broad range of topics. The papers apply behavior modification principles to remedial education, marriage and sex counseling, drug abuse, child rearing, and various psychiatric problems.

Topics covered include: treating anxiety; modification of maladaptive social and somatic behaviors; modification of preacademic and academic skills in children; behavior modification with disturbed children; modifying behavior of retardates and psychotics; modifying drug-related behavior problems; theoretical and ethical issues; training behavior therapists; and control and countercontrol: a panel discussion.



1975, 554 pp., $28.50/ £13.70

Prices subject to change without notice.

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety or agitation with depression

Triavil® 4-25

Each tablet contains
4 mg perphenazine and
25 mg amitriptyline HCl

a formulation particularly suited to psychiatric practice when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl

TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and that the full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude, muscle weakness, mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of tricyclic antidepressant poisoning. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

Released from symptoms of psychotic depression...

Productive again.

By helping to reduce the frequency and intensity of psychotic symptoms, Navane (thiothixene) often permits resumption of more normal, more productive living.

The antipsychotic effectiveness of Navane—with relatively little drowsiness—helps patients remain more active, more alert, better able to meet the ordinary demands of life.

Cardiovascular side effects such as hypotension and nonspecific EKG changes are relatively rare with Navane (thiothixene). Extrapyramidal symptoms have been reported, but are usually controlled by reduction in dosage and/or administration of antiparkinson drugs.

Once you've controlled acute psychosis or psychotic depression, some patients can be maintained on a simple once-a-day dose. This once-a-day regimen can reduce the risk of missed doses with no loss of efficacy.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Navane®

(thiothixene) (thiothixene hydrochloride)

Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg/Concentrate 5 mg/ml

Once-a-day–to help control symptoms of psychosis

For prescribing information, including adverse reactions and contraindications please see following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg (thiothixene hydrochloride) Concentrate: 5 mg/ml, Intramuscular: 2 mg/ml

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children–The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution–For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate–In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor elevating action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg, of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

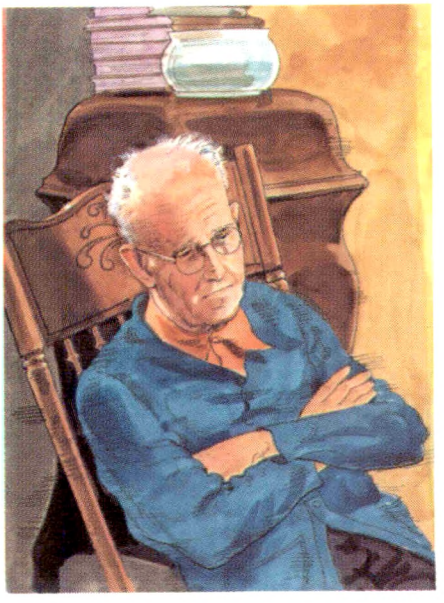
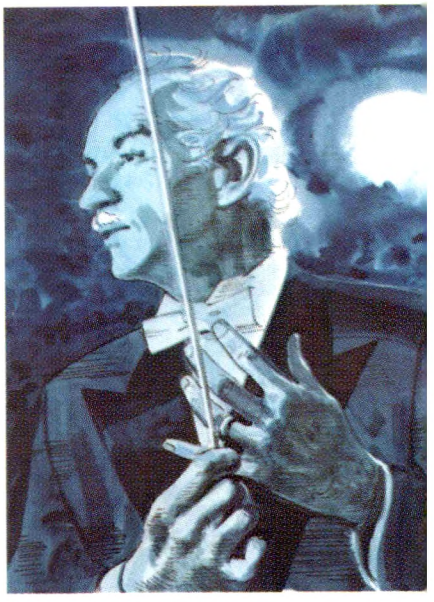
Adapting to age: time and the mind

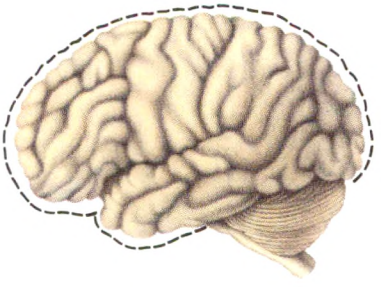
Aging successfully: is the goal just survival?



Popular belief would have it that "aging" and "existing" are the same, both marked by deteriorated ability—physical and mental. But is successful aging just existing?



Or is it making the most of one's abilities?



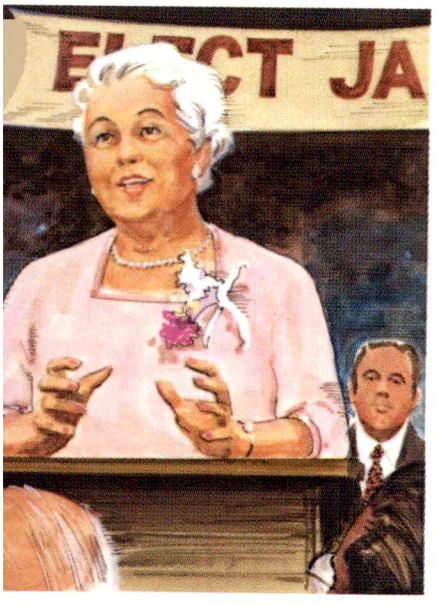
More than just surviving the changes and obstacles of old age, successful aging is *adapting* to the changes and *overcoming* the obstacles. Consider the very fortunate aging individuals who continue active, productive, even socially significant lives. Picasso, painting and sculpting until his death at the age of 91. Stokowski still conducting at 92. Margaret Mead, an active author and anthropologist at 73. Consider, too, those who lack prominence and popular acclaim, but still lead personally satisfying lives. Thus adding meaning to their prolonged existence by following interests and abilities.

How then, can some age so successfully, others less so, and still others merely survive? One reason: individual differences. Not only in abilities, but in opportunities and situations that can either nurture or suffocate ability.

Aging doesn't have to mean ailing bodies and failing minds. True, the cell loss of old age extends to the brain. But

the loss of brain cells doesn't invariably lead to loss of intelligence and alertness. For,

Although the decrease in brain volume is well known, enormous reserves of cerebral cells help compensate for loss with age. Disease and injury, more than advancing age, actually lessen cerebral capacity.



And lack of use contributes to the decline; mental and physical functions that are utilized tend to persist and thos not utilized tend to disappear. So, if usec the mind often can remain alert. Anc in fact,

Some now believe that intellectual decline can be minimal.

One theory isolates two basic types c intelligence: "fluid" and "crystallizec Both increase into adolescence, but flui intelligence, formless and independer of education, begins to decline durin the twenties. Crystallized intelligence - experience refined through education - continues to grow, and does not declir or even level off during old age. Sc according to this theory, total intelligenc changes qualitatively. Quantitatively, remains relatively constant.

But we still see senility and seemin mental decline, sometimes caused b

njury to the brain from accident or a lisease like cerebral arteriosclerosis. In ome cases, the reason may be per- onality frustration even more than ctual brain deterioration: a decline in *erformance* generated by severe stress nore than a decline in *cognitive ability.* Clinically significant anxiety, alone or as- ociated with underlying organic dis- ase, is common in the elderly, and can ripple the aged mind, and interfere with ne adaptive process. But

When such anxiety is controlled the elderly patient may become more responsive to personal interests and social activities. To therapy and counselling. To adapting to the changes of age.

If antianxiety therapy adjunctive to your counsel and reassurance is desirable, consider Serax (oxazepam). Serax has been found valuable, particularly in the older patient, in the management and control of clinically significant anxiety, tension, agitation and irritability.

Special care must of course be taken in prescribing antianxiety agents for elderly patients, especially where cardiac complications might ensue from a drop in blood pressure. And careful attention must be paid to dosage recommendations and follow-up observation.

More than eight years of clinical experience have shown Serax to be especially useful in many geriatric patients. Its dosage flexibility* generally permits adjustment to individual patient needs, making Serax a logical choice in the management of clinically significant anxiety in the elderly patient.

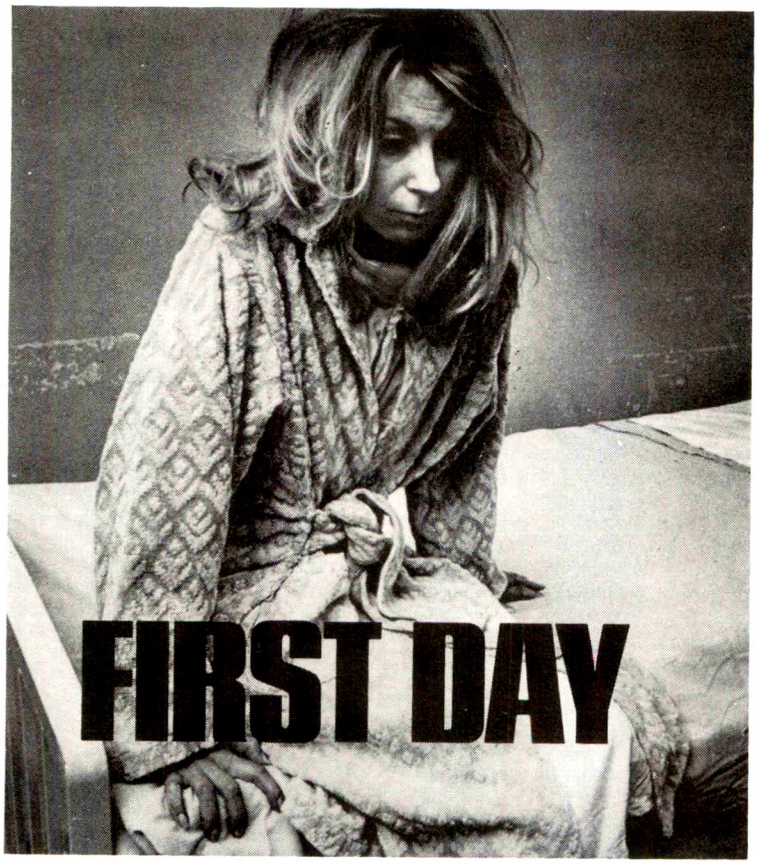
In Brief.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease. Anxiety associated with depression is also responsive to oxazepam therapy. This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients. Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

*See package circular for full prescribing information.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: Use in Pregnancy. Safety for use in pregnancy not established.



Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance. Not indicated in children under 6 years; absolute dosage for 6- to 12-year olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

Wyeth Laboratories · Philadelphia, Pa. 19101

Wyeth
makers of Serax® (oxazepam)
for use in clinically significant anxiety

First day in the hospital and all efforts will be directed toward returning her to the community.

For psychotic patients with mixed anxiety-depression, Mellaril has been found useful to help patients participate more fully in the entire therapeutic program. Continued medication with Mellaril is often basic to helping patients prepare for and participate in outpatient treatment programs that bridge the gap between hospital and community.

With Mellaril, patients are generally alert and in better contact with reality and can more fully benefit from the entire therapeutic program. (In the hospital or out, even though Mellaril produces only minimal sedative effect, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, a distinctive feature of Mellaril is that extrapyramidal stimulation —notably pseudoparkinsonism—is minimal.

MELLARIL®
(THIORIDAZINE)

TABLETS: 25 mg., 50 mg., 100 mg., 150 mg., and 200 mg. thioridazine HCl, U.S.P.

helps in the management of psychotic patients with mixed anxiety-depression

Before prescribing or administering, see Sandoz literature for full produc information. The following is a brief summary.

Contraindications: Severe central nervous system depressior comatose states from any cause, hypertensive or hypotensive hear disease of extreme degree.

Warnings: Administer cautiously to patients who have previousl exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaur dice) to phenothiazines. Phenothiazines are capable of potentiatin central nervous system depressants (e.g., anesthetics, opiates, a cohol, etc.) as well as atropine and phosphorus insecticides. Dur ing pregnancy, administer only when the potential benefits excee the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopeni and/or agranulocytosis and convulsive seizures. In epileptic pa tients, anticonvulsant medication should also be maintained. Pig mentary retinopathy may be avoided by remaining within the rec ommended limits of dosage. Administer cautiously to patients par ticipating in activities requiring complete mental alertness (e.g. driving), and increase dosage gradually. Orthostatic hypotensio is more common in females than in males. Do not use epinephrin in treating drug-induced hypotension since phenothiazines may in duce a reversed epinephrine effect on occasion. Daily doses i excess of 300 mg. should be used only in severe neuropsychiatri conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especiall with large doses, early in treatment; infrequently, pseudoparkin sonism and other extrapyramidal symptoms; nocturnal confusion hyperactivity, lethargy, psychotic reactions, restlessness, and head ache. *Autonomic Nervous System*—Dryness of mouth, blurred vi sion, constipation, nausea, vomiting, diarrhea, nasal stuffiness and pallor. *Endocrine System*—Galactorrhea, breast engorgement amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*- Dermatitis and skin eruptions of the urticarial type, photosensi tivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Ef fects* below). *Other*—A single case described as parotid swelling.

The following reactions have occurred with phenothiazines an should be considered: *Autonomic Reactions*—Miosis, obstipation anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfolia tive dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocy tosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplasti anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of elec trocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with pheno thiazines, including Mellaril (thioridazine); these appear to be re versible and due to altered repolarization, not myocardial damage While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, severa sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardio graphic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathi sia, agitation, motor restlessness, dystonic reactions, trismus torticollis, opisthotonus, oculogyric crises, tremor, muscular rigid ity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhyth mical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk be ing greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Dis- turbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpy- rexia; behavioral effects suggestive of a paradoxical reaction, in- cluding excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythema- tosus-like syndrome.

THE AMERICAN JOURNAL OF PSYCHIATRY

The Psychotherapist's Search for Self-Renewal

BY TRACEY MCCARLEY, M.D.

The role of psychotherapist carries with it special stresses to which many professionals react with depressive feelings, particularly in mid-life. Psychotherapists who participated in small group sessions at two annual institutes of the American Group Psychotherapy Association revealed their depressive feelings in a striking way. Some were able to relate these feelings to early family dynamics that motivated their choice of a caretaking career. The groups concluded that there is a continuing necessity for the caretaker to acknowledge and seek care for his emotional needs. Planners of continuing professional education for psychotherapists should make these needs a central concern.

THE NOTION THAT the role of the psychotherapist carries special stresses is a truism that we all acknowledge. We accept the beginning therapist's need for personal therapy to help him master and use his empathic understanding of his patients and of the individual and group process and to aid him in handling his personal conflicts. However, the therapist's need for emotional support and reclarification and renewal of self-understanding in the later years of his practice is inadequately recognized. Perhaps the disturbingly high number of suicides among psychiatrists could be reduced were it not for the prevalent feeling that what was acceptable in the early years of training is not acceptable in mid-career. In "Analysis Terminable and Interminable" Freud (1) recommended that the psychoanalyst "enter analysis once more at intervals of, say, five years, and without any feeling of shame in so doing." But Freud's advice in this regard is rarely followed.

There are formidable internal and external forces opposing the mature, practicing psychotherapist's return to therapy or analysis. The internal factors include the feeling of humiliation or embarrassment at again identifying oneself as a "patient" and the reluctance to assume a dependent role. The external deterrents include the problem of having social relationships with the colleagues to whom one might choose to go for therapy. A further difficulty is the prevailing myth expressed in the statement, "He was analyzed by so and so." The implication is that the process has been completed and that it is a reflection on either the analysand or the analyst if further therapy is undertaken.

Dr. McCarley is in private practice at 4911 Van Nuys Blvd., Sherman Oaks, Calif. 91403; he is also Associate Clinical Professor of Psychiatry, University of Southern California School of Medicine, Los Angeles.

THE NEED FOR SELF-RENEWAL

Stresses of Middle Age

Erikson (2) has shown us how different stages of life present us with different adaptational tasks. This means that the solution one has worked out in analysis or therapy during the training period may not be appropriate for coping with what Marmor (3) has called the crisis of middle life. Marmor pointed out that in mid-life come such stresses as the physical signs of aging, i.e., the loss of hair and skin tone and the battle against weight gain, intimations of one's own mortality, and the deaths of friends and relatives. During this period, one very powerful stress for most people is the recognition that they may never achieve the high goals they had set for themselves. And all of these stresses come at a time when there is the greatest demand on one's earning capacity to meet the needs of the family, including school-age children.

When one adds to these the kinds of stresses inherent in the practice of psychotherapy, i.e., the daily confrontations with patients' depressions, rages, and demands for support and nurturance, it is obvious that one has a formidable emotional load to carry.

A positive reason favoring the return of the psychotherapist in mid-career to some form of renewing emotional and educational experience is the fact that having now dealt with a great number and variety of patients, he has a rich lode of experience, counterreactions, and countertransferences to examine and learn from. In this area, introspection can carry one just so far, and there comes a

time when the calm view of a colleague with no personal ax to grind is needed to restore perspective. This view can be provided by the special relationship that we call therapeutic but by other settings as well. The kind of group experience described in this paper could be useful periodically to almost all therapists, and it might provide a kind of "preventive maintenance" that would make formal therapy unnecessary.

Group Experiences

Group experiences of various kinds are currently very popular with psychotherapists. They frequently attend weekend workshops, marathons, encounter groups, etc., which are held at training centers, nearby resorts, or right at home when a traveling exponent of one of the "newer methods" comes around. The practicing therapist's wish to learn something about Gestalt therapy, transactional analysis, or some other technique may fuse with his legitimate need for some "emotional feeding" and a chance to reexplore feelings. More traditional meetings, with their rigid formats, do little to fill the need that some of these newer group experiences try to meet.

In contrast to the short-term, intensive nature of the weekend meeting is the leaderless therapy group of experienced psychoanalysts reported by Kline (4). Kline felt that the once-a-week meetings of this group, which continued for three years, were successful in facilitating the further maturation of these already trained psychoanalysts.

There are many other situations in which a psychotherapist may find the opportunity to ventilate and reexamine his feelings, i.e., at lunch with colleagues and at committee meetings, but it is the clinical group at the annual institute of the American Group Psychotherapy Association (AGPA) that I would like to examine with these considerations in mind. My experience indicates that a substantial number of the participants in this annual activity of the AGPA come with a consciously articulated goal of "learning something about group therapy," but their more important, although unconscious, goal is to receive some attention for their more personal emotional needs and conflicts. Psychotherapists tend to feel an excessive responsibility for helping people, and they have a proclivity for spurring themselves to greater and greater effort to "rescue" their patients. This paper will present some observations made on a few therapists in a short-term, intensive educational group experience.

In this group the more pronounced depressive trends in some of the older members were matched by similar dynamics in some of the younger participants. From this interaction there developed a dominant group theme that has an urgent relevance to our profession's plans for continuing education programs and projects.

OBSERVATIONS

The clinical group at the annual institute of the AGPA is composed of no more than 15 participants who have indicated on their applications their desire for a learning experience that will include, to varying degrees, both didactic and experiential components. These applicants are matched with a group leader who has indicated on his questionnaire that he favors a comparable mix of the two elements. For the two consecutive years that I conducted the clinical group I indicated my expectation that the principal type of learning would be experiential but that there would also be a substantial amount of time devoted to didactic material. Sometimes it was not possible to match the preferences of the applicants and group leader. Hence some of the group members had requested a more didactic type of leader. At the other end of the continuum were a number of participants who had stated that they came to have an "emotional experience." The majority, however, had simply indicated that they came to learn about group therapy, a modality with which they had limited experience.

Both years the clinical group met morning and afternoon on two consecutive days for sessions of three or four hours in duration. I told the group at the beginning that our purpose was to learn about group therapy by experiencing, observing, and reflecting together upon what happened in our group during the two days that we were together. In each of the meetings, after the group had worked for a while on a theme, I called a halt to the interaction and invited the members to reflect on what had happened. It is some of the material that came out before this point, when the group was functioning as a working therapy group, that led me to the conclusions regarding depression that I have stated.

The dominant theme that emerged each year concerned the participants' oppressive feelings of being overwhelmed by the responsibilities of caring for psychiatric patients and their deep feelings of discouragement.

The First Year

During the first year this theme emerged as one group member, a psychiatrist in his early 50s, described his reasons for coming to the institute. He came to learn about group therapy so that he could add this technique to his therapeutic armamentarium. He said that he felt discouraged with what he was able to do for his patients and wanted to learn about group therapy so that he might be able to be more helpful to them.

As he talked, his sense of discouragement and depression became more apparent. As this feeling was explored he began to talk about his situation back home, where he had become a sort of father-confessor to almost everyone, it seemed. He spoke of his professional colleagues and their wives and families, all of whom came to him with urgent personal crises. Since he had assumed this role in the small community, he felt there was no one to whom *he* could go to talk about his feelings. He had had some therapy many years earlier, but he now was in partnership with the man who had been his therapist, so he did not want to talk with him about his feelings of discouragement and deprivation. He was in a kind of downward spiral in which the more depressed he felt, the more he had to spur himself to try to do more for others. The more he did for others, the more deprived he himself felt.

In the group he became more aware of this strong feeling of deprivation and realized that he seldom asked for attention to his own needs. He found it hard to accept the view, which was expressed almost unanimously by the group, that he appeared depressed. However, after some gentle insistence, he began to accept the idea that his needs had as much validity as those of his patients. He began to see that he was living by a kind of double standard since he took the stance that his patients should accept without shame their need for help, but he could not do this himself.

This man's discussion of his dilemma sparked another participant's statement that she felt she was also shouldering too great a load of responsibility in her life because her husband was so passive and ineffectual. Her revelation came in a dramatic outburst of tears that ended her almost two days of maintaining a facade of bright, brittle confidence. The group, following my lead, tried to convey to her the idea that she would be more comfortable with herself and more effective with her clients if she did not have to expend so much energy in maintaining such a carefully made up, false front.

The group concluded with a discussion of the process by which these revelations came about. And the theme was expressed that very often those who assume the helper role have difficulty accepting their own need for help.

The Second Year

At the AGPA institute the following year, in an entirely new group, this same theme emerged even more dramatically, with a larger number of participants revealing personal material relevant to it.

The denial by one of the participants that she ever felt anxious or depressed about her patients was irksome to the others, and they and she became irritated with each other. Eventually she angrily accused me of trying to make her be a "patient." Several participants then expressed the view that being a patient was a humiliating thing. At that point I said that it need not be seen as shameful and that I thought of myself as a patient from time to time as I worked on some problem with my feelings. This comment seemed to change the whole atmosphere in the group. Everyone relaxed a bit and began to speak more freely and with more expression of feeling.

A man began to talk about his feelings of being burdened by the expectations of his family and his wife's family. They thought that he should handle all of their emotional and marital problems because he was a psychotherapist. Another man said that he always had been the most successful person in his family and that because of this he was expected to take care not only of his mother's and his ne'er-do-well brother's emotional problems, but their financial ones as well. He was at that moment struggling with their implicit demand that he move them to the state where he lived so he could look after them.

A third group member, an older woman, spoke of her feelings of being trapped because she was the one of her sibship who had taken on the job of living with and caring for her elderly mother. She described a life in which she devoted her working hours to caring for patients and then came home in the evening to care for her invalid mother. She had, or rather took, little time for friendships or social life. It appeared that her decision to come to the AGPA institute to participate in a group sprang from an unconscious, or at least only partly conscious, wish to meet some of her own emotional needs rather than her strictly educational ones.

The Need To Give and Receive Care

In each of the two groups under discussion, a majority of the participants clearly indicated that they identified to some degree with this theme of feeling overburdened with a need to give. This identification was revealed by verbal contributions, repeated nods of agreement, or rapt attention. Two or three of these participants had been in practice for many years and were at a mid-life crisis. Others were younger but nevertheless had very similar dynamics. There were one or two others who seemed less involved in this issue. It was clear that they had quite different personality dynamics. For instance, one of these was a psychiatrist in an administrative position in a drug rehabilitation program. He did not seem to understand what we were talking about and was quite antagonistic at having been placed in a group where there was so much emphasis on the expression of here-and-now feelings.

Nevertheless, all but a small minority agreed on what might be called the "caretaker's need to be cared for." The group consensus that we should all accept this need within ourselves without shame produced an almost tangible sense of profound relief in the room.

DISCUSSION

These and other experiences in leading groups of psychiatric residents and other psychotherapists, as well as introspection into my own unconscious, have led me to formulate some hypotheses relating to common psychodynamic mechanisms in some professional psychotherapists. Understanding these mechanisms helps to explain the phenomena that I observed in the clinical group of the AGPA institute. My conclusions are as follows.

There are deep-seated, unconscious reasons, rooted in family dynamics, that motivate a person's choice of a caretaking career role such as that of psychotherapist. A significant number of psychotherapists are drawn to the role of caretaker because they were assigned this function early in life in their families. The role of caretaker allows for some symbolic gratification of one's own needs through identification with the client or patient to whom one is giving. And, over time, a fairly stable balance may be struck between giving care to others and receiving care. However, this balance is frequently precarious because the originally assigned role carries with it a proviso that the caretaker must be the "strong one" who keeps out of consciousness *his* need to be cared for.

At any stage of life, but particularly at mid-life, this precarious balance may be upset—by the loss of a sup-

portive relationship, disappointment in one's ability to help in certain situations, or by other factors. At this point the caretaking professional person may become depressed. If he can allow himself to acknowledge his depression, he can seek therapy or other ways of meeting his perceived needs. If, however, he cannot admit such a need to himself, he must seek help in a disguised form. This is precisely what I think a certain number of applicants to the AGPA institute are doing.

For these psychotherapists, as well as for those with other motivations for becoming caretakers, the opportunity to reexplore their feelings periodically in the supportive, therapeutic atmosphere of a group may be very desirable, not only for the therapist's personal comfort but so that he can function better in his role with his patients. The needed experience does not have to be therapy per se; it may instead be in a new kind of continuing education for which we as yet have no satisfactory name. It may be in the form of refresher courses or periodic peer supervision sessions in which the planners and leaders consider that attention to the emotional needs of the therapist is not only a legitimate but a central focus of the work.

We are now experiencing a growing recognition of the need for continuing education for professionals of all kinds. In planning the continuing education of those who devote most of their professional lives to psychotherapy it must be recognized that the psychotherapist uses his feelings, his self, to a degree that is unique. And that self has to be adequately cared for to function well.

Cocaine Psychoses: A Continuum Model

BY ROBERT M. POST, M.D.

The author describes an orderly progression of clinical syndromes (euphoria, dysphoria, paranoid psychosis) with cocaine use that is related to dosage, chronicity, and genetic and experiential predispositions. That affective alterations are caused by a drug which also produces a schizophreniform psychosis suggests a continuum with implications for understanding the endogenous psychoses. The author emphasizes that alterations in the same neurotransmitter substances may be involved in these multiple psychiatric syndromes, which contrasts with previous "one illness, one transmitter" models.

PHARMACOLOGICAL MODELS AND HYPOTHESES of psychiatric illness have tended to focus on the idea of a single biochemical disorder in a single psychiatric illness. However, the finding that multiple psychiatric syndromes can be associated with a single drug—cocaine, for example—has received scant theoretical attention.

The amphetamine psychosis model has implicated dopamine (1–3), the 6-hydroxydopamine self-stimulation model has implicated norepinephrine (4), and the lysergic acid diethylamide model has implicated serotonin (5) as significant single neurotransmitters in schizophrenic illness. Similarly, single deficits or excesses of specific catecholamines or indoleamines have been postulated in depressive and manic illness (6–9). This kind of pharmacological specificity in theorizing about psychiatric syndromes undoubtedly has utility and heuristic value, but it may also partially obscure the importance of observations relating the same compounds to different illnesses. For example, chronic administration of L-dopa to neurological and psychiatric patients has resulted in the precipitation and/or exacerbation of several different kinds of psychiatric syndromes, including depression, mania, and acute psychosis (10–13). Similarly, in a particular set of circumstances, cocaine can be associated with a syndrome of manic-like euphoria, depressive-like dysphoria, or schizophrenic-like paranoid psychosis (1, 14–22), the symptoms of which are presented in appendix 1.

The potential for stimulants to induce euphoria or dysphoria as well as a schizophreniform psychosis has not been systematically included in the theoretical formulations of "model" psychoses. This paper will review the different syndromes evoked by cocaine and some of the important determinants of response, including drug administration variables (especially dose and duration), underlying genetic and experiential components, and acute clinical-state variables. It will emphasize the progressive evolution of the cocaine syndromes from euphoria to dysphoria to paranoid psychosis as cocaine effects increase in increasingly vulnerable individuals. This progression suggests that alterations in the same neurotransmitters may be involved in each of the cocaine-induced syndromes.

It is suggested that consideration of the different psychiatric syndromes evoked by a pharmacological agent might yield information about the determinants underlying the differentiation and expression of analogous spontaneous or stress-related syndromes. Study of the biological mechanisms related to cocaine-induced behavioral changes may also be relevant to non-drug-induced behaviors. The idea that pharmacopathogenicity may recapitulate psychopathogenicity will be explored. It should be emphasized that this paper makes no claim that cocaine can induce or precipitate mania, depression, or schizophrenia per se, for in several respects cocaine-induced symptomatology does not perfectly mimic that of the functional psychoses. It is suggested, however, that the cocaine syndromes mirror many aspects of the endogenous psychoses closely enough to warrant comparison and that the model derived from such study may be useful in conceptualizing biochemical-behavioral interactions. In addition to cocaine, L-dihydroxyphenylalanine (L-dopa), methylphenidate, and the amphetamines have been implicated in manic-, depressive-, and schizophrenic-like syndromes and will be referred to when clinical data on cocaine are incomplete.

COCAINE EUPHORIA

As described initially by Freud (16), ingestion of from 50 to 100 mg of cocaine hydrochloride is accompanied by a profound sense of elation, increased mental agility, and physical endurance. Freud stated:

> I take very small doses of it regularly against depression ... with the most brilliant success. [The effects were] exhilarating and lasting euphoria, which in no way differs from the normal euphoria of a healthy person.... You perceive increase in self-control and possess more vitality and capacity for work.... This result is enjoyed without any of the unpleasant after effects that follow exhilaration brought about by alcohol.... Absolutely no craving for the further use of

Revised version of a paper presented at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

> cocaine appears after the first, or even repeated, taking of the drug. (23, pp. 54, 56)

Cocaine's mood-elevating properties have been lauded by the Inca Indians in the 1600s and the drug culture of the 1970s, which heralds it as the euphoriant of choice—"king cocaine" (24). However, clear-cut mood elevation was not demonstrated when cocaine was administered orally in doses recommended by Freud to 10 moderately to severely depressed patients hospitalized at the National Institute of Mental Health (NIMH), although one patient did have brief periods of hypomania during cocaine administration (25).

After subcutaneous administration of many sympathomimetic amines, the effects of which are subjectively undifferentiable from those of cocaine, addict volunteer subjects experience a profound euphoria (26). Intravenously injected cocaine produces an ecstatic high which is of brief duration but is so intensely pleasurable that the user may repeatedly "shoot-up" at intervals of 10 to 15 minutes, expending his entire cocaine supply over several hours (14, 21).[1] In studies at NIMH in which 12 depressed patients were given cocaine intravenously, only one experienced a pure euphoria and an anesthetic sense of relief from problems, unaccompanied by dysphoric components (25). This euphoria was experienced after a small dose of cocaine (5 mg), which caused only mild changes in pulse and blood pressure. Although in this case the clinical trial was immediately discontinued and placebo infusions were substituted, it has been reported that typical manic-like symptoms may emerge after higher doses or more chronic cocaine administration, including intense garrulousness, hyperactivity, insomnia, mood lability, predisposition to violence, and grandiose delusions (27). In fact, early workers labeled the symptoms of cocaine abuse "cocainomania" (27). Increased sexual arousal may also accompany cocaine use (14, 15, 17, 19, 21).

COCAINE DYSPHORIA

In a prior study of orally adminstered cocaine in depressed patients, only 1 of 10 became significantly more depressed, agitated, and mute (25). This occurred, however, during a second trial with higher doses of cocaine after an initial trial with lower doses had been without antidepressant effect. Increasing anxiety, suspiciousness, and dysphoria have been reported after increasing doses of injected cocaine (14, 18), and this may partially account for the frequent simultaneous use of opiates with cocaine to modulate and mellow its effects. High doses of stimulants pharmacologically related to cocaine (amphetamine and methylphenidate) also reportedly produce consistent increases in rated dysphoria and nervousness when administered subcutaneously to addict volunteer subjects (26). Cocaine self-administration in animals decreases as the dose of cocaine per injection is increased (28–30).

An intense mobilization of affect and tearfulness was frequently observed in depressed patients receiving intravenous doses of cocaine sufficient to substantially increase pulse and blood pressure (25). Crying started abruptly, coincident with the peak changes in vital signs. The intensity and uncontrolled nature of the reaction as well as frequent attention to issues of sadness and loss were perceived by some depressed patients as dysphoric and were reflected in increased ratings of depression, sadness, anxiety, and difficulty concentrating (25). (At lower cocaine doses associated with milder changes in vital signs, positive affective responses to intravenous cocaine were more likely.)

It is doubtful that dysphoria associated with peak stimulant effects is in any direct way analogous to the dysphoria of the endogenous depressive syndrome, but it may be related to that seen in the subgroup of agitated depressed patients and to the depressive affect so commonly admixed with acute, fulminant manias (31, 32). Mania that has prominent dysphoric components is the most likely to progress to a point where it is difficult to differentiate from acute paranoid schizophrenia.

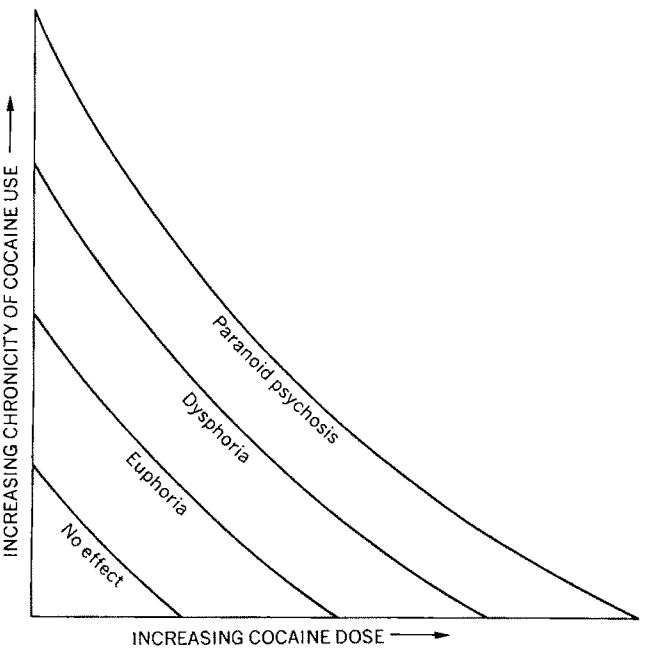
With chronic cocaine abuse, a syndrome of insomnia, painful delusions, apathy, and melancholy can occur (18). It should be noted that these depressive-like symptoms are noted during cocaine administration and that withdrawal phenomena (which are interesting in their own right) are not being referred to here. A dysphoric phase has also been documented in the studies of experimental induction of amphetamine psychosis in addict volunteer subjects (33–36). This phase occurs during the transition from initial euphoria to paranoid psychosis. In one study, a period of clear depression was also noted in all six volunteers who ingested more than 50 mg of *d*-amphetamine (33).

> That is, they became quite hypochondriacal, spent much of their time in bed, lost interest in TV or ward activities, were anorexic, irritable, fault-finding, and would relate to personnel in a clinging, dependent manner. This dysphoric affect was modulated, however, and responsive to external events. (33, p. 901)

Patients then entered a prepsychotic phase during which they became taciturn, seclusive, and preoccupied with details of their rooms or of the study procedure (33).

COCAINE PSYCHOSIS

When cocaine is abused chronically, a paranoid psychosis that is almost indistinguishable from acute paranoid schizophrenia (14, 19, 36) can result. After acute intravenous cocaine administration, the development of a paranoid psychotic state (referred to by users as the "bull horrors" because of intense fear of police) can occur even more rapidly than after amphetamine administration (37). After chronic cocaine administration, delusions of persecution may be vague or systematized and may be



[1]The large total amount of cocaine that can be administered in this fashion has been mistakenly accepted as evidence for tolerance.

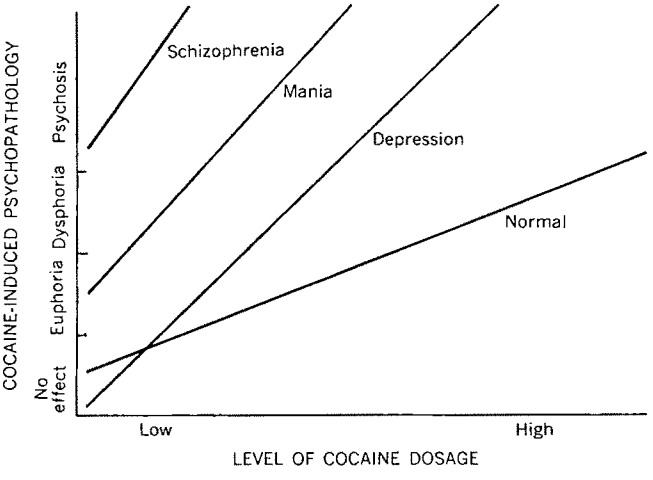
accompanied by auditory, visual, or olfactory hallucinations. The user has a clear sensorium and is not confused or disoriented as in a toxic psychosis or delirium, which can also occur after an overdose but is of less theoretical interest. A peculiar but infrequent aspect of the cocaine psychosis is the delusion of parasitosis and sensations of insects under the skin (formication) which may lead addicts to repetitively pick at their skin (36). Addicts may even probe their skin with needles for "cocaine bugs." The addict may experience

> irritability, erroneous conclusions, suspicion, bitterness towards environment, a false interpretation of things, groundless jealousy. . . . A cocainist who has snuffed 3.25 gr. cocaine armed himself for protection against imagined enemies . . . another broke furniture and crockery to pieces and attacked a friend. (27, p. 84)

Violent behavior may be prominent during the height of the cocaine psychosis, apparently triggered by paranoid trends. Stereotyped compulsive behavior analogous to that seen in experimental animals can develop. Addicts may repetitively pursue the same task and be endlessly absorbed by minutiae, as depicted in the case of Sherlock Holmes (38). Hallucinations usually stop when use of cocaine ceases, but delusions may persist.

FIGURE 1
Interaction of Dose and Chronicity in Cocaine-Induced Psychopathology

DETERMINANTS OF COCAINE RESPONSE



Drug Administration Variables

From the foregoing descriptions, it is clear that increasing the dose and/or chronicity of cocaine administration is associated with increasingly severe affective and cognitive alteration (see figure 1). Initial effects in the euphoric spectrum give way to dysphoria with increasing cocaine use; the paranoid psychosis is reached after high dose and/or chronic administration. At the highest doses, a toxic delirium, convulsions, and death from cardiorespiratory arrest can occur.

The relationship may also be summarized by organizing the response to cocaine along the continuum proceeding from euphoria to dysphoria to psychosis. Again, a positive correlation of cocaine dose and severity of disorganization is suggested (see figure 2). Chronic compared to acute cocaine administration in each case would increase the slope and shift the curve to the left toward greater disorganization at a given dose. Parenteral compared to oral administration would similarly shift a given dose-duration curve toward increased likelihood of euphoric, dysphoric, and psychotic reactions at a given dose.

The rate of change of drug effect appears to be a particularly important determinant of cocaine effect. The "rush" may be related to initial rapidly occurring changes, while the cocaine-induced tearfulness and mobilization of affect in depressed patients corresponds with peak cocaine effects as determined from pulse and blood pressure (25). Delusional thinking and aggressive behavior after amphetamine use are often related to sudden rather than gradual increases in dose (39).

FIGURE 2
Hypothesized Interaction of Dose and Psychiatric State in Cocaine-Induced Psychopathology

Predisposition

In addition to factors related to drug administration, a series of variables relating to a patient's personality and experiential-genetic predispositions seems crucial in determining the response to a given agent. Freud was cognizant of the importance of these factors in relation to cocaine's effects, stating,

> I could not fail to note, however, that the individual disposition plays a major role in the effects of cocaine, perhaps a more important role than with other alkaloids. The sub-

> jective phenomena after ingestion of cocaine differ from person to person, and only a few persons experience, like myself, a pure euphoria without alteration. Others already experience slight intoxication, hyperkinesia, and talkativeness after the same amount of cocaine, while still others have no subjective symptoms of the effects of cocaine at all. (16, p. 16)

This experience is consistent with the finding in depressed patients of varied psychological and physiological responses to intravenous cocaine, where the minimal dose that increased pulse and blood pressure 10 points ranged from 2 mg to 16 mg (25). It would be important to distinguish effects related to differences in blood levels and metabolism of cocaine from those related to differences in patients' sensitivity or predisposition.

Differences in genetic or experiential predisposition can clearly alter one's response to a drug such as L-dopa (10). Depressed patients with a past history of mania (bipolar) uniformly responded to therapeutic trials of L-dopa with hypomanic episodes; patients without a history of mania (unipolar) did not become hypomanic in response to L-dopa (10). Genetic determinants of responses to stimulants are also highlighted by the demonstration of significant differences in hyperthermic response to amphetamine in different genetic strains of mice (40). Prior experience might also predispose selective behavioral response to the drug either on a pharmacological or conditioning basis. Kramer (39) observed that once a patient experiences a paranoid decompensation on amphetamine, even a small dose of the drug taken after a prolonged abstinence may be associated with a recurrence of a paranoid reaction.

Clinical State

Superimposed on genetic and environmental predisposing factors are those relating to the acute clinical status of the patient, such as the type of psychiatric illness, the degree of recent stress or loss, the occurrence of a vulnerable phase of a circadian or ultradian rhythm, and, of particular importance in clinical trials, the patient's expectations or set in the context of a given experimental setting (41). The chronicity of stress would also be an important determinant of the response. For example, acute social stresses in rats, such as fighting and overcrowding, lead to increasing excitation, depletion of norepinephrine, and probability of death after amphetamine administration (42). Chronic social stresses in rats, such as living in groups and being the recipient of peer aggression, are associated with behavioral resistance to amphetamine and altered amine response (42, 43).

On the basis of the observation that a regular, predictable progression (euphoria, dysphoria, psychosis) occurs with increasing intensity of cocaine effect, it is suggested that preexisting, active psychopathology would alter the dose-pathology relationships as depicted in figure 2. For example, an acute schizophrenic patient would have baseline psychotic symptomatology prior to drug use and would further disorganize in the psychotic spectrum after stimulant administration; therefore, he would not experience typical euphoric-dysphoric effects. This schema would also predict that the psychotic decompensation would occur at lower doses than in a healthy individual. Similarly, a manic patient's dose response prediction would begin in the euphoric-dysphoric range, reflecting preexisting psychopathology, and stimulants would exacerbate the manic state, ultimately leading to psychotic disorganization at relatively lower doses than for normal individuals. Figure 2 suggests that, to a certain extent, depressed patients might require a higher cocaine dose to achieve initial euphoric effects than would well individuals, but a lower dose to exacerbate dysphoria. It might also be predicted that patients who are clinically well but predisposed to mania, depression, or schizophrenia would tend to be more sensitive to cocaine than the nonpredisposed subject as depicted by a steeper slope in figure 2.

Although there is not a great deal of systematic data relating clinical state to cocaine response, various predictions depicted in figure 2 have been supported in patient populations studied with drugs similar to cocaine, such as amphetamine (36) and methylphenidate (44). For example, Janowsky and associates (44) reported that changes in psychosis ratings from baseline to 15 minutes after receiving .5 mg/kg methylphenidate were greatest in acute schizophrenic subjects, less in manic subjects, least in depressive subjects, and absent in control subjects. Also consistent with the schema presented was the finding that remitted schizophrenic, manic, and depressive subjects showed proportionately less psychosis after methylphenidate than the respective groups of actively ill patients, but still more than normal subjects (44).

DRUG MODELS OF ENDOGENOUS STRESS

Might we not consider this formulation, emphasizing the varieties of psychiatric response to a single drug, as a model for naturally occurring, stress-induced responses? It would appear that the stimulants, such as cocaine, may be particularly useful models for endogenous stresses. Many of the biological changes associated with cocaine administration appear to mimic those often associated with stress. Cocaine has a generally alerting, sympathomimetic, predominately catecholaminergic action (14, 45, 46). Its acute versus chronic administration may affect neurotransmitter levels and turnover in ways parallel to that of acute and chronic stress. In the most global terms, acute stress tends to increase discharge of catecholamines while chronic stress tends to deplete amines (47). Preliminary evidence indicates this pattern may also occur with amphetamine-like stimulants (48). Finally, cocaine appears to have the intriguing property of reverse tolerance, i.e., increased effect after repeated administration of the same dose (49–52).[2]

It is possible that the progressive disturbances of mood and cognition with increasing cocaine administration and

[2]This property of cocaine may bear certain similarities to the "vicious circle" or positive feedback aspects of some psychopathological adaptations wherein stress may increase the vulnerability to further stress.

the drug and patient variables that affect them may be useful models for the progression of endogenous psychotic disturbances and their mitigating clinical factors. If this line of reasoning has some validity, it might suggest that some of the variables determining the type of psychic response to cocaine-like stimulant drugs would also be important in determining the response to stress. The severity and chronicity of stress in an appropriately susceptible individual might then help predict the type of psychiatric syndrome that would be produced in a manner similar to that suggested for cocaine. Certainly, one of the issues for further investigation based on the pharmacological model presented here would be the possibility of a stepwise continuum for the manic, depressive, and schizophrenic psychoses. The overlapping clinical symptomatology in the acute psychoses and the derived continuum models have been discussed by others (53). The new concepts derived from the cocaine model are 1) the orderly progression of symptomatology, 2) the importance of shifts between affective and schizophreniform states, and 3) the possibility that subtle differences in the same transmitter substances may be related to the different illnesses.

BIOCHEMICAL CORRELATES

Cocaine potentiates the effects of norepinephrine, dopamine, and serotonin at the synapse by blocking reuptake of neurotransmitter into the presynaptic ending (14, 54). It has other direct pre- and postsynaptic effects on several neurotransmitter systems (25). Cocaine, therefore, has complicated and multiple effects even on the better explored transmitters, and the relative role of a given amine in the euphoric, dysphoric, or psychotic syndrome is not yet known.

The finding that drugs with different chemical structures (cocaine, amphetamine, L-dopa, phenmetrazine, and methylphenidate) have all been associated with the onset of schizophreniform psychoses (and euphoria and dysphoria) suggests that the effects are not related to a specific toxic metabolite of one compound (35, 55) but rather to mechanisms of action they have in common. This would also be suggested by the finding that many of the effects of these drugs on human and animal behavior are inhibited by blocking catecholamine receptor sites (neuroleptics) or catecholamine synthesis (α-methyl-p-tyrosine [AMPT]). Cocaine and compounds with related effects enhance dopamine at the synapse either by increasing synthesis, blocking reuptake, increasing release, or stimulating dopamine receptors. They also have effects on noradrenergic as well as serotonergic and cholinergic systems (1, 42–46, 56, 57). Thus, the recent formulations of the amphetamine model psychosis linking one transmitter (dopamine) to one illness (schizophrenia) should be extended (1).

The same transmitter (dopamine) may be linked to the euphoric-dysphoric syndromes as well as paranoid psychosis. The well-known clinical data that neuroleptics are effective in mania as well as schizophrenia (and that selected agents such as thioridazine may possess some efficacy in depression) support the idea that the same pharmacological mechanisms may be involved in several of the endogenous psychotic syndromes.

Other transmitters affected by cocaine (norepinephrine and serotonin) may similarly influence specific components of both the affective and schizophrenic illnesses. The cocaine model presented would thus emphasize the role of neurotransmitter substances in relation to each other, their relative balances, and the time course of their alterations as being critically involved in the regular progression of behavioral change, rather than a "one amine, one illness" formulation. For example, one hypothesis to be tested further is that a relative predominance of noradrenergic to dopaminergic effects may be associated with the early euphoric effects of cocaine, while the ratio might be reversed later corresponding to cocaine's psychotogenic effects.

Animal Models

Cocaine's dramatic effects on animal behavior make it well suited for dissection of biochemical-behavioral relationships. It is noteworthy that cocaine produces hyperactivity at low doses in many laboratory species, compulsive stereotypes at higher doses, and, with chronicity, cataplexy (52). Thus, clear sequential changes are also observed in animals after increasing dose and duration of cocaine. While the direct comparison of these behaviors to human clinical symptomatology remains a dubious proposition, the unraveling of their biochemical determinants may provide valuable clinical leads. For example, an inhibitor of catecholamine synthesis, AMPT, decreases cocaine-induced hyperactivity and stereotypy in the rat, while an inhibitor of serotonin synthesis, p-chlorophenylalanine, does not (58). AMPT also blocks stimulant-induced euphoria in amphetamine addicts (59). The involvement of cholinergic transmission is highlighted by the demonstration that physostigmine, an inhibitor of acetylcholine esterase, will also block cocaine-induced hyperactivity (58). These effects are of particular interest because physostigmine acutely blocks manic behavior in patients with affective illness and also blocks stimulant-induced psychotic disorganization in schizophrenics (60, 61).

Study of acute and chronic cocaine administration in nonhuman primates is currently in progress in order to evaluate behavior in a species closer to man and to assess simultaneous alterations in catecholamine and indoleamine metabolism (62). Preliminary observations indicate that, much like humans, different monkeys appear to have individual styles of response to cocaine and that the same dose of cocaine administered chronically produces a progression of effects from a hyperactive-stereotypic reaction to an inhibitory reaction with catalepsy, hallucinatory-like glances, and an increased susceptibility to cocaine convulsions. Cocaine can also induce seizure activity that is confined to limbic system structures such as the olfactory tubercle, nucleus accumbens, and amygdala and is associated with profound behavioral change and not with convulsions (63–67). A further linkage of

cocaine-induced limbic seizure activity and psychopathology is the observation that drugs which alter cocaine seizure threshold have major psychotropic effects (neuroleptics and thymoleptics), while routine anticonvulsants (diphenylhydantoin and phenobarbital) do not significantly affect cocaine seizures and are not useful antipsychotic agents. Pharmacological or functional disconnection of cortical-subcortical integration due to altered limbic system activity could profoundly affect cognitive and affective integration in the cocaine and functional psychoses.

Thus, consideration of the physiology and anatomy as well as the pharmacology of cocaine's effects may add the extra spatiotemporal dimensions necessary to define more specific biological-behavioral correlates. Under specified conditions, cocaine can produce different clinical syndromes that occur in a regular sequence (euphoria, dysphoria, psychosis) with increasing cocaine administration. Such a progression from affective to schizophreniform syndromes has clinical and biological implications. It is a fascinating prospect that a drug popularized by Freud and described both as a "gift from the sun god" and as the "third scourge of mankind" may play a role in the definition and integration of biochemical, anatomical, physiological, and host interactions in the spectrum of psychoses.

APPENDIX 1

Symptoms of Cocaine Clinical Syndromes

Cocaine euphoria
- Euphoria
- Affective lability
- Increased intellectual function
- Hyperalertness
- Hyperactivity
- Anorexia
- Insomnia
- Hypersexuality
- Proneness to violence

Cocaine dysphoria
- Sadness
- Melancholia
- Apathy
- Inability to concentrate
- Painful delusions
- Anorexia
- Insomnia

Cocaine schizophreniform psychosis
- Anhedonia
- Lack of disorientation
- Hallucinations
- Concern with minutiae
- Stereotyped behavior
- Paranoid delusions (parasitosis)
- Insomnia
- Proneness to violence

A Multidimensional Problem-Oriented Review and Evaluation System

BY SHELDON I. MILLER, M.D., AND ROY H. SCHLACHTER, M.S.W.

The need for evaluation of psychiatric services is becoming more and more apparent as third-party coverage becomes more available. A variety of expensive and complex data and computer systems have been developed. Small institutions and programs, however, cannot afford them. The system described in this report uses diagnosis and a standardized problem list in order to define the treatment outcome of a variety of therapies delivered in an interdisciplinary setting. The system, which has been developed and is operating at low cost, satisfies a variety of needs.

WITH THE ADVENT OF increasing pressures for peer review of psychiatric treatment, the importance of building a method of evaluation into a delivery system is becoming more clear. Currently, most efforts in peer review are being directed toward inpatient populations, but the interest in outpatient care is evident as well. Much of the federal government's interest in this area centers around cost containment; this can easily result in the simple counting of either average days of stay in the hospital or average number of visits per diagnosis for a hospitalized or an ambulatory patient. It is therefore incumbent upon the profession to develop a more multidimensional approach to the evaluation of both inpatient and outpatient care.

A number of sophisticated and rather costly systems have been developed that collect extensive data and function as a direct aid to the care provider as well as being useful in evaluation procedures (1–5). However, since the total mental health field faces the need for evaluation of its service delivery, it is necessary to develop a variety of low-cost, yet comprehensive, data and evaluation systems that can serve these functions more generally. The system to be described in this report is one such example. It functions as the primary data collection and evaluation tool for a department of psychiatry in a large general hospital affiliated with a medical school; the department primarily serves ambulatory patients.

The authors are with Cleveland Metropolitan General Hospital, 3395 Scranton Rd., Cleveland, Ohio 44109, where Dr. Miller is Associate Director, Department of Psychiatry, and Mr. Schlachter is Project Director, Evening Mental Health Clinic. They are also with Case Western Reserve University School of Medicine, where Dr. Miller is Associate Professor of Psychiatry and Mr. Schlachter is Instructor in Psychiatry.

DEVELOPMENT OF THE SYSTEM

When the department was established about five yea ago, it was decided that from the outset a system woul be established that would allow for evaluation of servic functions and treatment outcome. The department composed of individuals representing different thec retical orientations toward psychological processes. It interdisciplinary in function and professional compos tion (6); social workers, psychiatrists, psychologists, an nurse-clinicians all act in a generalist role as well as in th specialist roles specific to their training and backgroun Each individual acts as the primary evaluator and defin tive therapist for a variety of patients. Patients are a signed to the staff on a rotating basis unless the initial r ferring information indicates a specific need for psychiatrist, social worker, psychologist, or nurse. Whe necessary, the special expertise of another professional requested in consultation. It is sometimes necessary t transfer the primary responsibility for a patient to ar other professional. This diversity served as an adde stimulus to our desire to be able to evaluate the effectiv ness of the individuals approaching similar problem from different points of view.

The diversity in staff composition is matched by a d versity in the patients seen. The department operates a active consultation service, day and evening outpatie facilities (7), childrens' services, a satellite clinic that geographically separate from the institution, and an alc holism program. Because of this diversity in service th patients seen represent virtually every diagnostic en tity (8).

Our goals in developing a review and evaluation sy tem for this department were multiple. We wanted 1) simple demographic description of the patient popu lation, 2) a tool for evaluating outcome, 3) a managemer tool, 4) a means of gathering information that would hel in planning programs on the basis of current experienc and 5) a way of determining cost effectiveness without n glecting the details of the patients' actual needs and prob lems. We wished to accomplish these goals with a min mum of professional time so as not to unduly raise th staff's resistance to the evaluation. Similarly, we did n want to increase the cost by using undue amounts of pr fessional time in record-keeping. It must be pointed ou that our goals did not include, as in some systems (1, 3 providing aids in diagnosis or replacing the writte record with machine-generated records. Coloring all

the development was the ever-present reality that the cost of the system had to be kept under the $10,000 that was available for the project.

SYSTEM INPUT

Perhaps the most difficult problem was to develop a way of briefly describing a patient at the time of his initial evaluation so as to be able later to measure the treatment outcome. Diagnosis alone was felt to be insufficient, since in many cases it did not adequately describe the patient's reason for seeking help and his source of discomfort. Many things could cause someone with the diagnosis of schizophrenia to seek help, and although upon completion of treatment the diagnosis might still be appropriate, the patient's situation might have improved considerably. Diagnostic evaluation was therefore coupled with Weed's concept of the problem list (9).

Over a period of six months each staff member recorded the presenting problems of each patient seen. At the end of the six-month period the problems generated from all divisions within the department were reviewed. By combining similar problems, a standardized 72-item problem list was created. One category, "Other," was included with a space for narrative description. The items entered in this category can be periodically checked and the list revised in light of current clinical practice. In general, the list excludes diagnostic entities. However, problems such as depression, which at times are symptoms and not diagnoses, are included (see appendix 1).

A standardized list was necessary in order to permit retrieval of information and comparison of those data with other variables. The presenting problems of each patient as well as diagnostic impressions (up to three for a given patient) are recorded at the time of evaluation. The diagnoses are entered and stored as primary, secondary, or tertiary.

In addition to these data, a variety of other information is gathered during evaluation. Basic demographic data including social class (10) are recorded by the secretarial staff before the patient is seen for evaluation. The initial evaluator's discipline (social worker, psychiatrist, etc.) is specified, as are other treatment data. The evaluator is asked to specify the treatment to be used (drugs, individual psychotherapy, etc.), the proposed duration of that treatment (i.e., the number of visits), time spent on the initial evaluation, and other agencies or individuals who might be involved in the treatment.

This form is the first part of a two-part input system. The second portion is completed at the time treatment is terminated. The termination form, which is brief, gathers information about the treatment and its outcome.[1] The discipline of the final therapist is also recorded. Comparison of the disciplines of the initial evaluator and the final therapist allows a determination of how often one member of the interdisciplinary team refers a patient to another.

Other data recorded include the actual number of visits, method or methods of treatment used, specific names of any medications prescribed, final diagnosis, which when compared to the initial diagnosis allows some measure of diagnostic accuracy and consistency, initiator of the termination (patient, therapist, etc.), and a statement of outcome. The outcome judgment is made subjectively by the therapist on a five-point scale ranging from "much improved" to "much worse." It is made separately on two different features of the case. First, a statement concerning outcome for the patient's presenting problems only is made, and second, an evaluation of the patient's more global diagnostic condition is recorded.

Both the initial evaluation information and the termination outcome information are stored on a disc and entered by means of a keyboard-equipped cathode ray terminal connected to an IBM 370/155 computer. Information is entered directly into the computer through typewriter keyboard manipulation of a marker moving across the television image of the form being entered. The data are filed by hospital number, and each new patient creates a new file. Once the information from the initial evaluation form is entered into the computer, the form itself becomes the face sheet for the patient's clinical file. In this way the data are made immediately available to the therapist without our having to develop the costly capability of immediate communication with the computer. Similarly, at termination of treatment that form is filed in the patient's chart so that all data are available if the case should again become active.

SYSTEM OUTPUT

Two different types of outputs are routinely available. One is a report by divisions within the department. Each month, each division receives a summary of its data for that month and for the year to date. In addition, a total output for the department is generated. This report is simply a numerical summary of the items entered in the system. This relatively simple report allows comparisons among departmental divisions. It supplies data useful in planning program expansion, deployment of personnel, effort expended in a variety of different therapeutic modalities, description of the patient population, etc. It does not, however, furnish the data necessary for evaluation and comparison of the effectiveness of various treatment modalities, professions, etc. A more complex report is therefore required to meet other goals of the system.

The output most helpful for this review and evaluation is generated upon request for a given time period. A list of 72 standard multidimensional comparison programs is available.[2] Others can be specially programmed as needed. It is possible through these comparisons to satisfy all of the original goals of the system as well as many others. For example, program 49 ("Complaint—Psychiatric Service—Initial Diagnosis—Final Diagnosis—Proposed Visits—Actual Visits") allows a variety of com-

[1]The forms are available from the senior author on request.

[2]The list is available from the senior author on request.

parisons. This program allows a differentiation of diagnostic groups into smaller groups based on the patient's presenting complaint. It is then possible to compare the number of visits required by patients in these diagnostic subgroups. Furthermore, it is possible to compare the performance of the different divisions within the department. This can be done in relation to the divisions' expectations (proposed visits) as well as to their actual process (actual visits). If differences are found, other comparisons can be made to help isolate factors influencing the observed differences. If no differences exist, then a standard of practice within the department becomes evident.

DISCUSSION

The total system has been in operation since January 1972, although its development took approximately one year. As of April 1974, 4,660 patients were included in the file. The developmental costs of this system were kept under $10,000. This relatively low initial cost is matched by an equally reasonable annual maintenance cost. At present, all desired reports as well as minor program changes and additions are provided at a cost of less than $5,000 per year.

The system has already aided patients and staff in a variety of ways. Because of the evaluation data available, we are attempting new approaches to patients whose problems have not been resolved. For example, we found that we were seeing a large number of young women with the presenting complaint of depression. Therapeutic efforts with this group failed to produce a level of success with which we were satisfied. We are therefore currently in the process of establishing a group program designed to determine whether a feminist approach to this population (i.e., independence versus dependence, mastery versus powerlessness) will be more effective than a more traditional approach. Our standardized problem list has aided us in defining the actual stresses that cause people with given diagnoses to seek help. In this process the variability of initial diagnostic impressions versus final diagnosis has become obvious.

Some divisions in the department are funded by outside sources. We have satisfied the funding bodies' questions, and this has resulted in continued and increased support. A satellite clinic has been established in an area identified by the system as containing a high proportion of our patients. The list of standard multidimensional programs enables us to calculate average utilization of service, defined not just by diagnosis but also by other variables such as problems, outcome, and therapist.

Despite the benefits, problems do exist in the system. Perhaps the major problem is using the therapist's subjective impression to rate treatment outcome. A "harder" measure of treatment outcome would be far more desirable, but it would also increase the cost of the system by increasing demands on professional time, computer time, and programming time. In practice, we have found that the major error made in rating a patient is for the therapist to be harder on himself than other members of the treatment team would be.

Another problem we had anticipated was that the standardized problem list would be incomplete, despite the six-month preparation time. In fact, we have found it to be about 90 percent complete. The list is about to be changed to delete items not used and to add items that were originally omitted. This is possible since we have stored in narrative form all problems listed in the "Other" category on the evaluation form.

In conclusion, this multifunctional, low-cost system is capable of meeting current review standards and of generating information that can make those standards realistic and patient oriented rather than solely cost oriented.

APPENDIX 1

Patient's Presenting-Complaint List

Abortion
Aggressive, out-of-control behavior
Anxious
Child abuse
Conflict with boyfriend/girlfriend
Conflict with governmental authority
Conflict with parent
Conflict with sibling
Conflict with spouse—marital problems
Death in family
Delusions
Depressed
Disorientation in person
Disorientation in place
Disorientation in time
Disrupted family (separation, divorce)
Disturbing fears
Drinking problem

Drug abuse
Employment problems
Fear of child abuse
Feeding problem
Financial problems
Grief reaction
Hallucinations
Head banging
Hearing problem
Homicidal attempt
Homicidal thoughts
Hyperactivity
Inadequate housing
Learning problem
Masturbation
Memory disturbance
Menstrual problem
Mental illness in family
Movement disorder
Nonorganic somatic symptoms coexisting with organic disease
Physical illness in family
Physical illness in self
Postoperative reaction
Pregnancy problems
Preoperative reaction
Problem in peer relationships
Problems with child
Problems with the law
Religious conflict
Repeated emergency room visits
Repeated hospitalizations
Rocking
School behavioral problems
Separation problem
Sexual, out-of-control behavior
Sexual problems
Social isolation
Somatic symptoms—no organic disease
  A. Dizziness
  B. Palpitations
  C. Headache
  D. Fainting
  E. Trembling hands
  F. Perspiring hands
  G. Respiratory irregularities
  H. Pain
  I. Numbness
  J. Other
Speech problem
Suicidal thoughts
Suicide attempt
Tantrums
Thumb sucking
Toileting problem
Trouble sleeping
Other (specify)

Ethical Issues in Family Planning for Hospitalized Psychiatric Patients

BY HENRY GRUNEBAUM, M.D., AND VIRGINIA ABERNETHY, PH.D.

The authors present guidelines based on their experience with a family planning program for patients in mental hospitals. They believe that informed consent for these patients should include an adequate knowledge base, the patients' competence to make decisions, and the absence of coercion. Among safeguards are the reversibility of contraceptive procedures, the separation of the family planning counselor from the treatment staff to avoid possible covert coercion, and careful choice of the stage of hospitalization at which counseling occurs. The authors examine the implications of a patient's refusal to use contraception, noting the impossibility of involuntary contraception and the ethical and legal problems regarding sterilization procedures.

PREVIOUS PUBLICATIONS by ourselves (1–3) and by others (4–6) have documented both the need to make family planning assistance available to patients in psychiatric institutions and patient receptivity to such programs. This paper deals with ethical issues encountered during two years of research and development related to the operationalization of a service that provides birth control and gynecological care in three state mental hospitals.

While some believe that family planning and contraception are inherently unethical, our program is based on our conviction that the individual has a right to control his or her own fertility. We will explore the problems that occur in the exercise of this right for mentally ill individuals. In each instance, we must take into account the rights of the patient, the unwanted child she may bear, and the larger society—rights that often appear to conflict. In addition, we will consider the relationship between the patient and the treatment staff of the mental hospital.

From the patient's point of view, particularly in terms of her civil rights, what is necessary is her informed consent. This involves three major factors: 1) adequate knowledge on which to base a decision, 2) competence to make a decision, and 3) absence of coercion in the decision-making process. Since the main purpose of a family planning program is provision of adequate information about the various contraceptive methods available, this aspect of informed consent does not present much of a problem in our program. However, competence to make such a decision becomes an important issue when the individual is mentally ill and her judgment and reasoning may be impaired. Finally, the mental hospital or clinic setting can be perceived as overtly or covertly coercive. We shall therefore focus our attention on the issues of competence and coercion.

It should be noted that the patient's civil rights and informed consent are not the only ethical values which must be considered. Her physical and mental health are also important. Society, for instance, is prepared to compromise civil rights when individuals undertake acts that will impair their own welfare too severely, such as self-mutilation or suicide attempts.

The benefits of contraception are obvious, and all known contraceptive procedures except sterilization (which our program does not provide) are reversible. Thus, a contraception decision made by a patient is not irrevocable. This fact may ameliorate the problems of competency and coercion (in ethical if not in legal terms), since the patient can reverse her decision at a later date.

SAFEGUARDS FOR PATIENTS IN MENTAL HOSPITALS

In order to give informed consent, a patient must have the capacity to make a sound judgment and must agree of her own free will to use contraception, knowing its risks and effects. For this reason, we will exclude from our discussion those instances when a decision is made by a guardian or parent for the patient and those in which a spouse or partner assumes responsibility for family planning.

In order to ensure that the patient has given informed and voluntary consent, we have confined our services to patients who are not acutely psychotic or confused. As patients improve from an acute decompensation, they become able to take care of themselves, resume their usual responsibilities, and spend increasing amounts of time outside the confines of the hospital. We do work with chronically psychotic women, taking into account the limitations inherent in their residual disability. We provide contraception only when the patient's psychiatrist gives permission, since the psychiatrist is in a good position to know whether she is capable of providing meaningful informed consent.

Dr. Grunebaum is Associate Clinical Professor of Psychiatry, Harvard Medical School, 74 Fenwood Rd., Boston, Mass. 02115, and Director, Studies in Population and the Family, Cambridge Hospital, Cambridge, Mass. Dr. Abernethy is Assistant Professor of Psychiatry (Anthropology), Vanderbilt Medical School, Nashville, Tenn., where she is also Director, Division of Human Behavior.

The authors are grateful to S. Bok, Ph.D., Jack R. Ewalt, M.D., Honora A. Kaplan, J.D., Prof. Lawrence Kohlberg, and the Rev. James A. O'Donohoe for comments on this paper.

Avoiding Coercion

Most patients today are admitted to Massachusetts mental hospitals voluntarily; few are involuntarily committed. If the hospital staff and family planning services exert no coercion on the patient, and if discharge, privileges, and other rewards are explicitly not made contingent on the use of contraception, consent can be considered to have been freely given. However, the subtle pressure of the hospital on even a voluntarily admitted patient is not to be underestimated. Even when no coercive intent exists on the part of the staff, patients may feel that they "have to do what the doctor says" if they are to receive his care and concern. Patients in state mental hospitals are dependent and, in many ways, powerless. In addition to the disadvantages inherent in mental illness, they often have additional disadvantages related to low economic position and lack of education. The stigma of the mental illness label also reduces their power. Mental patients are not in a position to "talk back"; they may not see themselves as free to refuse or withdraw from participation in family planning counseling. Because the counselor has the trappings of authority, it is not unusual for a patient to agree overtly, while evidencing covert disagreement by her behavior. Thus, the critical issue for the hospital staff is to avoid using its position coercively. One method we have employed is differentiating the family planning counselor from the treatment staff. In our program, the nurse-counselor plays no therapeutic role outside the area of family planning.

Reversibility

A second safeguard for the patient is the fact that all of the contraceptive methods we employ are reversible. We believe it is crucial that mental hospitals not offer sterilization or vasectomy to their patients. Patients who desire these services can be referred to an outside agency, but the hospital should play no role in promoting these nonreversible decisions.

Choosing the Proper Time

A third safeguard is to provide services for the patient at a time in her hospitalization when it is most probable that she can make a reasoned decision; i.e., when she is assuming increasing responsibility for the rest of her life, particularly her sexual relations. It would be paradoxical to permit a patient to decide to have sexual relations on an overnight or weekend pass and not permit her to decide to use contraception. Custodial hospitalization regulated patients' sexuality to a great extent; in community-based treatment, our attention must focus on patients' fertility.

THREE "COMPOSITE" PATIENTS

In order to focus our discussion, we shall describe three "composite" mental patients who exemplify the kinds of problems we regularly encounter in family planning counseling. The first patient is Miss Acute, a 17-year-old from a large poor family who made a suicidal threat when her boyfriend left her. She has had rather promiscuous and unprotected sexual relations and probably will continue to do so after her hospitalization, which will most likely be brief. The second patient is Mrs. Recurrent, age 35, who is married and has four children, the last of whom was clearly unwanted. She was admitted recently for her third hospitalization in a depressed and confused state. The third composite is Miss Chronic, age 32, who has been in and out of mental hospitals for 10 years. She occasionally works as a waitress and at other times is on welfare. Two of her four pregnancies were terminated by abortions; one of the two children she has borne is being reared by a sister, and the other was given up for adoption.

In our experience, it is likely that Miss Acute and Mrs. Recurrent will choose to use contraception. However, a closer look suggests that their complex situations are not so quickly resolved. Miss Acute may try to use the pill, but she may forget to take it regularly, perhaps in an unconscious or deliberate attempt to force her boyfriend to marry her. She may be motivated by her need to provide her mother with a child; she may seek to mother a child who is unconsciously seen as a mother to her; or she may act on the basis of a generalized self-destructive drive. Mrs. Recurrent will attempt to use an intrauterine device for a variety of possible reasons: e.g., pressure from her husband, who wants to discontinue using condoms, or awareness of her own ambivalence about using contraception regularly.

While the family planning counselor may believe that Miss Acute is acting in an ill-advised way and that Mrs. Recurrent is making her decision under pressure from her husband, their behaviors are both understandable and typical. Both of these women can give informed consent to the use of contraception, and only rarely will the mental health professional feel that such consent is unreasonable. The problem for the staff arises when a patient refuses contraception or is not adequately informed as to its risks.

Issues When the Patient Chooses Contraception

It is sometimes difficult to ensure that psychologically disturbed individuals fully understand the risks and complications of various contraceptive procedures—meticulous efforts are required. The issue is complicated by the fact that some patients do not want to know about the risks of contraception, just as medical patients often do not wish to hear about all the risks of an operation or the prognosis of an illness. This places the counselor in the difficult position of having to decide between the patient's chosen stance and informing her adequately. We believe that patients who are aware that there are risks involved in contraception but who make it clear that they do not wish to be burdened with the details of these risks have the right not to know.

The ethical issues raised when a patient consents to contraception include the questions of whether she: 1) is adequately informed about the risks and complications of the specific contraceptive she is using, 2) is competent,

and 3) gives her consent freely. There are no ethical issues relating to unconceived children and no societal responsibility for a child who might become a social burden. There is, however, the social need to ensure that individual liberty has been preserved and that the staff of the mental hospital has not used its position coercively. Mental patients (particularly those who are committed) lose certain freedoms, and all mental hospitals are inherently coercive to some extent, which tends to deprive their patients of choice.

Issues When the Patient Refuses Contraception

Although informed consent poses problems and requires safeguards, the major ethical dilemma in family planning for mental patients arises when the patient decides not to use contraception and, like Miss Chronic, has a history indicating that she is likely to become pregnant. Miss Chronic is capable of living outside the hospital at times and of having sexual relations, but her ability to mother a child is impaired. Another pregnancy may be disadvantageous for all involved. Even if the patient wants to become pregnant, those responsible for her care may not believe this to be in her best interest, since her hospitalizations are precipitated by pregnancies and mothering an additional child would be an unnecessary, stressful burden. Her child might have a greater than normal genetic predisposition toward psychopathology. In addition, he would either be reared by a mentally ill mother or given up for adoption or foster care, neither of which is optimal for his future adjustment. And finally, society would probably have to assume some of the financial and social burdens in this situation. The hospital staff, as the representatives of society, have direct responsibility for the welfare of the patient, and they may be reluctant to discharge her. They may fear she will be "taken advantage of," and continual hospitalization may therefore be used as a means of contraception. For all these reasons, the incentive of the counselor to act coercively and insist on contraception is powerful.

CONTENT OF COUNSELING

What is to be done about the problem of patients like Miss Chronic? One approach is to reevaluate the information that is provided to the patient regarding her situation. Complete information for consent purposes could include reminding the patient of a pattern in her past in which recurrences of her illness were associated with pregnancy. It could be indicated that she might find additional children too great a burden. This may not be necessary, particularly if her husband or partner is making efforts to ensure that she will not become pregnant. The problem is greater when the partner is casual or unconcerned with the woman's long-term well-being.

Genetic Risk

In addition to these patient- and partner-oriented aspects of information, there are two other issues that might be discussed in counseling. The first concerns the genetic risk to the child. Adequate genetic counseling should be part of a person's knowledge base in an informed decision. Clearly, if there was a history of genetic disease, such as hemophilia or Huntington's chorea, this information would be given to the patient. Such information should be given even when the risk of transmission is far less. (In all likelihood a patient would already know about such a problem.) The inheritance of mental illness is less clearly understood, but it now appears that what is probably transmitted is a tendency toward psychopathology, with the final outcome uncertain. It seems, however, that the children of parents with chronic or process schizophrenia are at some genetic risk. It is vital to note that while carriers of very serious genetically transmitted diseases may be discouraged from having children, society in no way prevents them from doing so, even though society bears some of the financial costs of their children's disabilities. Society took a totally different position concerning mental disabilities in the involuntary sterilization laws for the "insane" and "feebleminded." These statutes, while still on the books, were not utilized very often and are now used even less.

For the reasons we have described, it seemed to us that a discussion of genetic risk might be appropriate in family planning counseling, at least for mental patients with a diagnosis of chronic schizophrenia. Indeed, to avoid this issue might be to collude in the patient's denial of this risk and concern. However, this approach has been unproductive and has had little impact on the patients with whom it has been attempted because they lack the interest or sophistication to comprehend it. We have abandoned discussion of genetic risk unless the patient brings it up, which does happen with less disturbed women.

Environmental Risk

Discussing environmental risk with the patient may at first appear more problematic than discussions of genetic risk. The evidence for purely environmental disadvantage to children of mentally ill mothers is less clear-cut: the studies to date are of children who have been reared by their own parents, which confounds the influence of nature and nurture. These studies suggest that having a psychotic parent is associated with some disadvantages for the child, but they do not point to any clear-cut or inevitable result, particularly since the potential ameliorative influence of the other parent is an important factor.

We are unwilling to predict that a particular patient will be a poor mother, given our current knowledge and the possible detrimental impact of such a statement on a patient. However, we do find it very useful to ask and discuss with the patient such questions as, "What kind of a mother do you think you could be now?" These are questions most patients are already considering seriously, and they will often open up important, if painful, dilemmas. Some of the more seriously ill patients we have counseled deny that they have any concerns about their mothering capacity and refuse to discuss the issue. The child is seen as a plaything or possession. Often these women have had pregnancies terminated by abortions or have had children removed from their care by the state. We believe that it is

appropriate to discuss any such history with the patient. If the state has regarded her as an unfit mother in the past, then it may do so again in the future, given a similar pattern of maternal behavior. The problem for the mental health professional is that those facts which make it clear that contraception is appropriate are the most difficult ones to discuss with the patient, since they also may imply that she will be a "bad mother." Such discussions may also be perceived as coercive by the professional, i.e., they use facts to force a certain outcome. Environmental risk is thus one of the most difficult matters to discuss frankly.

Even when all the facts are presented clearly to the patient, there will be a certain number of instances in which contraception is refused and in which the mental health professional feels that a pregnancy is not in anyone's best interests: the patient's mental and/or physical health may be endangered, her child may be subject to genetic or environmental risk and in many cases should or will be removed from her care, and society may have to assume the burden of support for the child.

STERILIZATION AND OTHER ISSUES

For a variety of reasons, nothing can be done with regard to contraception in situations where a pregnancy seems most inadvisable and contraception is refused. It is a fact that all current methods of contraception are reversible: we have even seen psychotic women who have pulled out their IUDs. It therefore makes no sense to attempt to force patients to use contraception.

The situation may be otherwise with regard to sterilization. It has been suggested that the judicial determination of incompetency and the provision of a guardian may well be the most effective way to safeguard the patient's rights. However, we have not been impressed by the experience with judicial intervention in sterilization, and the inconvenience of the procedure has led to its being used infrequently. Beyond this, it is our experience that judicial hearings on mental health matters tend to be rubber stamps for the hospital. We have observed that members of these judicial boards are rarely the most competent members of the profession and, as is often the case with such bodies, their ties are more with their colleagues than those whose rights they should protect. In such hearings, the rights of minorities, the poor, and the uneducated are sometimes neglected.

Regardless of the decision about sterilization, it is clear that involuntary contraception is simply not possible. Pills can be thrown away, an IUD can be removed, and a patient need not return for her injection of progesterone.

GUIDELINES FOR COUNSELING

The position that we have finally evolved may be summarized in the following manner. To make an informed decision, the patient must have a careful and painstaking discussion with the family planning counselor of the risks and gains involved in whatever course she selects. The effects of various contraceptive methods must be explained and the risks to her and to her future children should be broached. The feelings of the patient should be elicited first, since concern about the ability to bear children and about one's effect on one's child are life-long issues for all parents.

It may be appropriate to indicate to patients that there is a tendency for mental illness to be inherited. Patients know that "the apple does not fall far from the tree." Similarly, it is important to consider with the patient her ability to care for a child at this particular time in her life. An appropriate approach might be, "Is this the time for you to have a [or another] child?" If previous pregnancies have been terminated by abortion or a patient's children have become wards of the state, these facts should be part of the information discussed to obtain informed consent. As we have noted, involuntary contraception is not possible and will probably not become so until and unless resource scarcity makes it necessary. Whether sterilization is the ethically appropriate next step is a matter for separate consideration.

CONSIDERATIONS FOR THE FUTURE

Difficult as they have been to formulate, the guidelines we have presented barely suffice for the present and may be called into question if resources become scarcer and therefore more expensive, with an ensuing fall in the standard of living for the majority of citizens. At this time, we fully anticipate increasingly widespread pressure for, and practice of, unregulated procedures. For example, the newspapers recently reported the sterilization of two retarded black adolescents, apparently without the informed consent of themselves or their families.

We feel that such unregulated procedures have dangers both for the individual whose civil liberties may be deprived and for the future of programs providing birth control resources to the mentally ill or retarded, which might be terminated due to extreme negative reactions. Therefore we urge continuing consideration that takes as its point of departure the logical distinction which can be made between the right to sexuality and the right to fertility. It seems to us that the "right" to procreate may be fairly questioned when there is high genetic or environmental risk of mental disability and when the prospective parents are unable to care for or adequately support children. Inevitably, one confronts the philosophical and pragmatic questions of whether there should be (or, on a continuing basis, can be) rights without responsibilities and how this issue can be adjudicated in a fair and humane manner.

Workshop on Writing for Scientific Journals

The 1975 annual meeting of the American Psychiatric Association will feature the seond annual workshop on writing for scientific journals, to be held from 9 a.m. to 5 p.m. on Sunday, May 4 (the day before the annual meeting begins). The workshop, cosponsored by APA and the American Medical Writers Association (AMWA), will offer practical information and instruction on four subjects: common writing faults, organizing medical reports, getting your words on paper, and submitting a manuscript. Work assignments, which will be sent to registrants before the meeting, will form the basis for initial discussions during the workshop sessions. The course will begin with brief introductory lectures by the AMWA faculty, who include Charles G. Roland, M.D., chairman of the Department of Biomedical Communications, the Mayo Foundation; Barbara G. Cox, medical writer, Instructional Development Section, the Mayo Foundation; and Martha Tacker, Ph.D., free-lance medical writer and editor. Following the lectures there will be small-group discussions on the four basic subjects. The workshop will conclude with a panel discussion in which participants will have the opportunity to question the editors of several psychiatric journals.

Registration is limited to 40 participants. All applications for participation must be received by April 7; the registration fee is $65. For further information on registration write to Charles G. Roland, M.D., Department of Biomedical Communications, the Mayo Foundation, Rochester, Minn. 55901.

One-Year Follow-Up of Hyperactive Boys Treated with Imipramine or Methylphenidate

BY PATRICIA O. QUINN, M.D., AND JUDITH L. RAPOPORT, M.D.

The authors report on a one-year follow-up of 76 hyperactive boys who had participated in a comparative study of methylphenidate, imipramine, and placebo. They found that there was a higher rate of discontinuance of imipramine than of methylphenidate in this sample and that both medications decreased the boys' rate of weight gain but had no significant effect on growth in height. This finding is of concern because larger doses than were used in this study are in use elsewhere. Teachers reported that the group of boys who had discontinued either medication showed continued hyperactivity and behavior problems in the classroom at one year. The two treatment groups showed continued improvement at one year in classroom and home behavior and did not differ significantly from each other.

THE STIMULANTS amphetamine and methylphenidate reduce restless and negativistic behavior in comparison with placebo in 70 to 80 percent of hyperactive children treated for 6 to 12 weeks (1). The fact that these drugs wear off rapidly and the finding (2, 3) that they have such side effects as anorexia, weight loss, and growth disturbances have caused clinicians to seek alternative agents to treat hyperactive children.

The tricyclic antidepressant imipramine was found useful first in treating childhood enuresis (4) and later in treating behavior and learning problems in children (5, 6). Minimal side effects occurred with doses of 25 to 75 mg a day. Higher doses of imipramine have also been used with some short-term success (7, 8) in treating school phobia and hyperkinesis. However, serious side effects have been reported (9, 10), and few long-term treatment data are available.

A recent study of 19 outpatient hyperactive boys (11) showed 174 mg of imipramine a day to be effective during an 8-week treatment period. However, 78 percent of this sample suffered weight loss. In a comparative double-blind study conducted for 6 weeks at our clinic (12), imipramine was found to be superior to placebo but less effective than methylphenidate, particularly for cognitive test measures. Weight loss occurred even though only 80 mg of imipramine a day was administered.

Because of the lack of information about long-term drug treatment of hyperactivity, we followed up the 76 patients who participated in the comparative study of methylphenidate, imipramine, and placebo (12). We were particularly interested in the growth of children remaining on the drugs, the long-term pattern of use of medication, and the behavior effect of continued drug treatment.

Ideally, randomly assigned placebo and drug-treatment groups should be available for long-term comparison, but such groups are ethically and logistically difficult to obtain. We therefore report data on the follow-up "drug history" for the sample as a whole and for two groups who continued their original randomly assigned medication (imipramine or methylphenidate). We included a comparison group in which medication was discontinued after 4 months or less in spite of an initial good response to medication as judged from the blind 6-week trial or a trial that was not blind following administration of placebo.

We believe that the methodological impurities of such a comparison are outweighed by the need for long-term follow-up reports. In addition, standardized tests, rating scales, and normative data make a comparative assessment of our populations possible and facilitate communication among treatment centers.

METHOD

The 76 patients who participated in the initial comparison of methylphenidate, imipramine, and placebo (12) were seen for 6 weeks during their initial drug trial. At the end of this period, the placebo group was assigned randomly to one of the two drug groups and another 6-week trial that was not blind was conducted. Drug management was then continued during the year by the family pediatrician in consultation with the Hyperactivity Clinic. The patients in the active drug groups were continued on their initial drug whenever possible.

Seventy-three (96 percent) of the children were seen with their parents for a follow-up evaluation after one year. Two of the families had moved, but they provided behavioral data through mail and phone contact. One family withdrew from the study. Height and weight measurements were made on all of the children by the same examining pediatrician (P.O.Q.) at the same time

of day and on the same scale used at the initial visit. A history of medication use during the year was obtained.

Parents completed the Conners Parent Symptom Questionnaire (PSQ) (13); teachers completed the Conners Teacher Rating Scale (TRS) (14). These scales contain 39 and 92 behavioral items, respectively, which are given weighted scores from 0 (not at all) to 3 (very much). Individual factors for conduct disorder and hyperactivity have been identified. A battery of psychological tests was repeated, including the Wechsler Intelligence Scale for Children (WISC), the Wide Range Achievement Test (WRAT), the Porteus Maze Test, and our own global clinical rating on a 6-point bipolar scale.

Patients were urged to continue initial active medication when possible; changes were made only when they were judged clinically necessary because of home or school pressure. Thus optimal clinical maintenance was continued by the family pediatrician throughout the year. Both imipramine and methylphenidate are used in our area; we are unaware of any general bias in favor of either by participating physicians.

RESULTS

Continuation of Medication

At one year, 23 of the 29 boys in the initial methylphenidate group (79 percent) had remained on that medication. Their mean daily dose was 20.65 mg ±8.56. Of 9 boys who were randomly assigned to methylphenidate after a 6-week placebo trial, 6 had continued on that medication until the one-year evaluation. Thus 9 boys out of 38 had discontinued methylphenidate during the year (2 for irritability and excitation, 5 for worsening behavior, and 2 because of parental disapproval of medication).

Thirteen of the 29 boys in the initial imipramine group (44 percent) had continued on imipramine for 12 months. Their mean daily dose was 65.4 mg ±19.2. Of 8 boys randomly assigned to imipramine after a 6-week placebo trial, 5 continued on that medication for the remainder of the year. Thus a total of 19 out of 37 had discontinued imipramine after an initial trial (7 for unchanged behavior, 3 for hypertension, 7 for irritability and temper tantrums, and 2 because of parental disapproval of medication).

We were interested in both growth and behavioral changes at one year in relation to drug treatment. While 75 of the initial patient group had been on some medication during the year, growth and behavioral changes were compared only for children initially assigned to the active drug group and continued on the same medication for one year (23 on methylphenidate and 13 on imipramine) and for a comparison group of 12 hyperactive children who had shown some clinical response to the drugs but had discontinued treatment because of parental concern over side effects or over continued drug use.[1]

[1]An earlier estimate of drug treatment status at 6 months (12) proved erroneous at one-year follow-up. More children had discontinued medication at one year than was known at 6 months.

Side Effects and Growth Change

For the children who continued to take medication, anorexia was the most frequently noted side effect (39 percent and 47 percent of imipramine and methylphenidate groups, respectively). However, occasional complaints of irritability (3 patients receiving imipramine) and overstimulation (2 patients receiving methylphenidate) were noted. No seizures were reported.

Height and weight measurements were converted to percentile scores based on age and sex for a normal population (15). These are shown in table 1. The 23 children on methylphenidate for 12 months lost about 8.8 percentile points in weight and gained about 3.2 percentile points in height. The 12 children on imipramine lost about 7.6 percentile points in weight and lost about 2.2 percentile points in height. The 12 children who had discontinued treatment within 4 months gained about 1.6 points in weight and lost about 1.5 points in height.

The methylphenidate group who received a daily dose greater than 20 mg showed a 15.4-point weight loss and a 3.0-point height decrease, compared with a 6.9-point weight loss and a 5.1-point height gain for the group taking 20 mg or less of methylphenidate daily ($t=2.36$, $p<.02$ for weight by Student's t test).

Statistical comparisons between drug groups and the untreated group are also shown in table 1. Both drug treatment groups had a significant decrease in growth rate for weight but not for height when compared with the group who had discontinued medication.

Behavioral Change

The striking clinical impression at one-year follow-up was that the boys in all three groups continued to have difficulties. Few children were considered symptom free, although 24 (31 percent) of the entire sample appeared improved or much improved. Few had sought other treatments; 3 families were counseled briefly for behavior management, and 3 children had been placed in special educational settings.

Of the 29 children who had tried either imipramine or methylphenidate and then discontinued medication, 12 were selected for a comparison group because they had discontinued medication within 4 months and had not resumed it and because they had shown some behavioral improvement with medication on an initial blind trial or subsequent trials that were not blind. The reasons for discontinuation of the drug were: parental disapproval (3 patients), hypertension (3 patients), and irritability (6 patients).

The behavior ratings of teachers and parents at baseline, at 6 weeks, and at one-year follow-up are shown in table 2 for the two treatment groups. Baseline and one-year follow-up ratings are given for those who discontinued medication.

The three groups did not differ significantly on baseline measures. The TRS factor IV, hyperactivity, tended to be lower for the imipramine group than for the others. The baseline scores for the 16 children from the original randomly assigned group who discontinued imipramine were

somewhat higher than scores of children remaining on imipramine, although not significantly so (t=1.40 by Student's t test).

At one year the groups did not differ on the parent ratings: all three groups were rated by parents as having a highly significant decrease in hyperactive and distractible behavior compared with their behavior at baseline. The untreated group, however, did not change significantly in teacher-rated classroom behavior, while the two treatment groups did. The two treatment groups were similar to each other in their one-year follow-up behavioral classroom ratings, as shown in table 3.

Psychological Testing

Scores on the WISC, WRAT standard scores, and Porteus Maze Tests did not differ at baseline or at one

year between the groups. Individual behavioral change did not correlate with changes on any of these tests for any group.

DISCUSSION

Both imipramine and methylphenidate were found to decrease the rate of weight gain for children receiving medication for 12 consecutive months compared with a treatment dropout group. This replicates previous reports for methylphenidate at doses above 20 mg (2, 3). Our finding of decreased weight gain with lower doses of methylphenidate may reflect the facts that our sample had not discontinued medication during the summer months and that most received medication in divided doses.

The decrease in weight gain with imipramine was surprising in light of the fact that the mean daily dose given our patients was smaller than that in use elsewhere. Although there was no height decrease with either drug, the children had received medication for only one year. Decrease in growth rate has been found in children who have received drugs for two or more years. The rate of growth should therefore be examined carefully for children receiving higher doses of imipramine for longer periods of time. The significant decrease in height for imipramine compared with low doses of methylphenidate is probably the result of sampling variation; this did not occur when the imipramine group was compared with the untreated group.

Significantly more children ($\chi^2=7.30$, df=1, $p<.01$ by chi-square test) discontinued imipramine than methylphenidate in spite of the clinical bias to have them continue. This is in agreement with the pilot study reported by Gittelman-Klein (8) in which most children with initial short-term response to imipramine could not be maintained on it because of their deteriorating clinical course. Similarly, although Waizer and associates (11) reported the superiority of imipramine over placebo throughout an 8-week drug treatment period, they also found that the teachers' global improvement ratings during the latter part of the treatment period did not show sustained improvement. The basis for this discrepancy is not clear, but it is possible that it reflects a decline in overall clinical status with continued imipramine treatment.

Methylphenidate has been shown to differentially affect dopaminergic rather than adrenergic function (16), while imipramine has little effect on dopamine uptake (17). The more general efficacy of methylphenidate at one-year follow-up, particularly for the more aggressive children in our sample, lends some indirect support to the idea that dopaminergic mechanisms are involved in the impulsive aggressive behavior disorders of childhood.

Behavioral changes are the most difficult to evaluate from the present data. All three groups were seen as improved by the parents. This may reflect the parents' desire to see the children's ongoing treatment (or lack of it) as successful. On the other hand, it may indicate an actual decrease in difficulty at home.

The two treatment groups had significant and similar decreases in classroom ratings of hyperactivity and conduct disorder. The teachers were unaware that a comparative study was in progress and were not the same teachers who had made the baseline ratings the previous year. Their ratings may therefore have been subject to less bias than the parents' assessments. It is possible, however, that as the children mature their restless behavior decreases first in the home setting and continues longer in the more structured classroom setting. The good responders to imipramine and the good responders to methylphenidate did not differ in any measure at one-year follow-up.

These data supporting the long-term effect of medication on classroom behavior must be interpreted with caution because the control group of treatment dropouts may have biased the results. Adverse home or school influences as well as the constitutional endowment of the child might have been confounded with discontinuation of treatment. It was our clinical impression, however, that concern about drug use or side effects was the chief

reason for discontinuing medication for this group. They did not seem to differ in other respects from the two treated groups.

A strength of the present study is that almost all of the initial responders to stimulants were followed for one year; their course may be representative of larger populations.

It is also important to note that while classroom hyperactive behavior decreased relative to baseline values for the treatment groups, the classroom ratings of these groups were high in comparison with the norms available for their age group according to Sprague and associates (18). We are also impressed with the relation of classroom structure to the teachers' behavioral assessment and complaints; this will be reported on in another paper.

We hope that continued reporting of objective rating scale data will allow clinicians and researchers to compare the initial severity of patient samples as well as long-term response to treatment or treatment combinations.

While our long-term data favor the stimulant drug, good responders to imipramine showed similar clinical response to the stimulant. The advantages of imipramine, which does not have to be given during school and does not wear off rapidly, may be important in some settings. Thus for selected individuals imipramine may be a useful alternative to stimulant drugs.

Personality and Behavior Patterns of Heroin-Dependent American Servicemen in Thailand

BY GEORGE KOJAK, JR., M.D., AND JOHN P. CANBY, M.D.

The authors compared a group of heroin-dependent American servicemen stationed in Thailand with a matched control group of men not dependent on heroin. The data gathered regarding social history, attitudes, work record, previous drug use, personality, and intelligence show significant differences between the heroin-dependent men and the control group in four areas: intelligence, work record, number of years of schooling, and number of drugs used before using heroin. The data suggest that many of the heroin-dependent men had difficulties related to a distant or negative relationship to their fathers; however, in contrast to previous studies of heroin addicts, they do not confirm a relationship between heroin dependence and any particular personality pattern.

SINCE THE UNITED STATES seems to be in the midst of a national epidemic of heroin abuse, it would be useful to have objective data regarding the heroin-dependent person's personality and behavior. Otherwise excellent studies have been limited because the only available subjects were long-term addicts who, in many cases, were from particular socioeconomic levels or geographic areas where social disintegration, crime, and poverty were given factors. The reported increase in prevalence of heroin addiction in a broad spectrum of social and geographic groups makes it desirable to investigate other populations in which heroin addiction has become more visible. A population of servicemen in areas where heroin is more easily available than it is in the United States would serve as such a population.

The population for our study encompassed members of the U.S. Army in Thailand and all military personnel in the Bangkok area. These men came from all geographic areas of the United States and from every social group. They were employed in a noncombat area and had a higher level of education than the average American man because of the nature of their jobs. In Thailand there were almost no practical difficulties in obtaining 98 percent pure heroin that was inexpensive.

All military personnel in Thailand submitted urinalyses several times a year. Anyone who appeared to be using opiates—by his behavior, by clinical examination, or by urinalysis—was evaluated by the Department of Psychiatry at the U.S. Army Hospital. A closely supervised staff working with small numbers of patients facilitated the cooperation of our subjects and the accuracy of data collection.

This report compares personality and behavior data obtained from the patient group with data obtained from a representative sample control group.

METHOD

Population Studied

The heroin-dependent group (N=25) was composed of men between the ages of 18 and 25 who had less than three years of military service, who had been in Thailand for at least two months, who had a positive urinalysis for opiates, and who had a history of daily use of heroin for at least one month. The majority had used heroin daily for three to five months.

A social work technician, who did the testing and collected the data, explained the nature of the study to these men; only two refused to participate. An explanation of the results of the MMPI was offered to encourage cooperation in being honestly self-descriptive. It was explained to the patients that participation would not influence their treatment disposition, and confidentiality was assured. Most of these patients reported symptoms of opiate withdrawal during hospitalization.

The control group (N=50) included men between the ages of 18 and 25 who had less than three years of military service and who had been in Thailand for at least two months. They were chosen at random from the complete rosters of the military units in the three areas where the heroin-dependent men were found—Bangkok, a base in north Thailand, and a base in the center of Thailand.

The social work technician personally invited each individual of this representative sample to participate in the study, explained the nature of the study, assured confidentiality, and offered the men the results of the MMPI. No one refused to cooperate.

Within two days of this invitation these men were

At the time this study was conducted, Dr. Kojak was Chief, Department of Psychiatry, and Dr. Canby was Commander, U.S. Army Hospital, Bangkok, Thailand. Dr. Kojak is now Chief, Group and Individual Treatment Section, Harborview Community Mental Health Center, Seattle, Wash., and Instructor, Department of Psychiatry and Behavioral Science, University of Washington School of Medicine, Seattle, Wash. 98195. Dr. Canby is now Commander, U.S. Army Hospital, Fort Huachuca, Ariz.

The authors would like to thank Steven L. Murphy, James Srihra, and Michael H. Potts for their technical assistance.

The opinions expressed herein are those of the authors and do not necessarily reflect the views of the Department of the Army or the Department of Defense.

tested by urinalysis. The tests were negative for opiate derivatives. The men gave negative histories of heroin use (except for rare experimentation), took the MMPI, and completed a social history questionnaire in the same manner as the heroin-dependent group. One man who had been invited to participate in the control group was discovered to be heroin dependent and was referred to the other group.

Apparatus

1. MMPI. The MMPI was chosen for use in this study because of its wide use for comparison purposes and for its acceptance as having some validity in measuring personality aspects in a broad way (1).

2. Shipley Institute of Living Scale (2). This brief intelligence test was chosen because of its ease of administration and reliability.

3. Social history questionnaire. With the help of Steven L. Murphy, we developed for use in this study a questionnaire regarding family, socioeconomic history, attitudes, history of difficulties with school or police, and drug abuse history.

4. Urinalysis. Urinalysis for opiate derivatives was carried out in the laboratory of the U.S. Army, using the free radical assay technique, gas liquid chromatography, and thin layer chromatography as described by Winter (3). The control subjects submitted their samples within 48 hours of invitation to participate in the study. Forty-eight hours is the conservative limit of time for the accuracy and reliability of the test. The heroin-dependent subjects submitted their samples upon admission to the hospital.

5. Work history. The social work technician interviewed each individual's work supervisor and asked a list of specific questions regarding his work history (see appendix 1). There were nine questions and a point was given for each positive answer, except for question 8, for which two points were possible. A perfect work score was 10. If prejudice or lack of knowledge on the part of the supervisor was apparent to the social work technician, someone in authority who was familiar with the individual's work habits was questioned instead.

6. Discipline record. The social work technician checked the individual's military record for Articles 15 and courts-martial while in Thailand. Article 15 is a formal but minor disciplinary action. No one in either group had been court-martialed.

Procedure

All tests and questionnaires were administered in the social work technician's office to groups of not more than two men. The tests were given to the heroin-dependent patients four to six days after admission to the hospital. By that time the patients were comfortable and had had no withdrawal symptoms for at least 24 hours.

The data were statistically analyzed using a chi-square test for two independent samples on the binary data. A two-tailed test was used to evaluate MMPI scores, years of schooling, work record, IQ, "closeness-to-parents" scales, number of drugs used, and a "father-distance" scale. A discriminant analysis was done on 10 of the variables.

RESULTS

Demographic Data

Unlike previous investigators (4–6), we did not find any significant correlation between urban background or minority group membership and heroin dependence: 32 percent of the heroin-dependent men (N=25) and 18 percent of the control group (N=50) came from a city of more than one million population; 28 percent of the heroin-dependent men and 24 percent of the control group were nonwhite.

The difference between our findings and those of other researchers may be due to the focus on nonwhite urban populations in the earlier studies. Such populations may have particular reasons for using heroin, but our data do not indicate any relationship between being nonwhite and from a large city and heroin dependence.

We were unable to determine the socioeconomic status of the families of 20 percent of the heroin-dependent men because they did not know their fathers' occupations or how much education they had had. We were thus unable to determine the relationship between heroin dependence and the socioeconomic status of the family. However, all of the men in both groups had sufficient income to provide for their ordinary needs and for some luxuries. The average rank was the same for both groups: E3 or E4. Thus the fact that these men used heroin did not seem to be related to current poverty or unemployment.

No differences were expected or found in regard to the marital status of the men in each group: 24 percent of the heroin-dependent men and 30 percent of the control group were married; 4 percent of the heroin-dependent group and 2 percent of the control group were divorced; 68 percent of both groups were single; and 4 percent of the heroin-dependent group and none of the control group were widowed.

MMPI Data

We found no significant chi-square relationships for any of the scales of the MMPI. Forty percent of the heroin-dependent group and 38 percent of the control group had two scales higher than the 70th percentile. Thus the groups did not differ significantly for psychopathology as measured by the MMPI (see table 1).

Previous studies (7–9) have found significant elevations of MMPI psychopathic deviate, hypomania, psychasthenia, schizophrenia, and depression scales of heroin addicts. These investigators have described the personality of the heroin addict as "severely disturbed," "immature," "oral-passive," and "psychopathic." Factors such as long-term addiction, geographic location, legal problems, and commitment to the Public Health Service hospital influenced selection in these studies. Perhaps these sample-biasing factors would tend to yield results suggesting a relationship between disturbed personality and heroin dependence.

TABLE 1
Mean MMPI Scores for Heroin-Dependent Subjects (N=25) and Control Subjects (N=50)

MMPI Score	Heroin Dependent Group	Control Group
Cannot say (?)	7.6	7.4
Lie (L)	3.8	3.4
Frequency (F)	6.4	7.2
Correction (K)	12.4	13.5
Hypochondriasis (Hs)	13.9	13.5
Depression (D)	21.3	18.6
Hysteria (Hy)	20.5	24.8
Psychopathic deviate (Pd)	24.8	23.0
Masculinity-feminity (Mf)	24.1	24.6
Paranoia (Pa)	11.8	10.1
Psychasthenia (Pt)	28.2	28.0
Schizophrenia (Sc)	28.5	30.2
Hypomania (Ma)	21.9	23.1
Social introversion-extroversion (Si)	25.1	25.8

Social History

Other studies (4, 10–12) have also described heroin addicts as being dissatisfied with their living and working conditions, as easily frustrated, and as having a low tolerance for frustration. Our data failed to support these findings. The great majority in both of our groups described themselves as satisfied with their work, their supervisors, life in Thailand, friends, and their relationship to the military service (see table 2).

Our data also failed to support previous studies (4, 11–19) that found heroin addiction to be associated with antisocial behavior even before addiction. One study (13) found addiction to be associated with antisocial behavior at a time (1914) when opiates were legal and inexpensive. A minority of our group of heroin-dependent men reported having "troublesome problems" with parents, school, teachers, or police. The heroin-dependent group did not differ significantly from the control group on these measures. Few of the men in both groups had had previous mental health care, and military records indicated that they had received few disciplinary actions (Article 15). No significant difference was found between the two groups for disciplinary actions.

The differences in our findings from previous studies can perhaps be attributed to the latter's focus on particular groups of addicts. These studies have involved individuals referred to the Public Health Service hospital, those with legal problems, or addicts residing in particular urban centers where the prevalence of antisocial behaviors was unusually high.

The groups in our study did not differ in regard to history of venereal disease. About half of the heroin-dependent men and half of the control group men had a history of venereal disease in Thailand. Thus at least half of the men in both groups were apparently sexually active. (Thailand is a country where such activity is very available and attractive.) This finding tends to discredit the idea that heroin-dependent men have difficulty with sexual functioning.

TABLE 2
Social History Variables in Heroin-Dependent Subjects (N=25) and Control Subjects (N=50)

Variable	Heroin-Dependent Group	Control Group
Percent generally unsatisfied		
With work	24	14
With relationship to supervisor	16	18
With life in Thailand	28	16
With relationships to friends	12	2
With relationship to Army	24	30
Percent having trouble during school years		
With parents	24	22
With school or teachers	24	16
With friends	4	4
With police	20	10
With school or police	36	22
Percent having had previous mental health care	8	10
Percent having received Articles 15	24	8
Percent having venereal disease in Thailand	52	50
Number of years of school completed	11.9	13.2*
Average score on work record questionnaire	6.2	8.1*
Average IQ	99.7	109.8**
Percent coming from broken homes	32	22
Average score on closeness-to-mother scale***	3.7	3.7
Average score on closeness-to-father scale***	3.08	3.24
Percent reporting fighting between parents	20	28
Percent reporting divorce of parents	24	16
Percent reporting others in family used alcohol or other drugs to excess	16	16
Percent reporting father died before they were 17	12	8
Percent reporting mother died before they were 17	0	8

* $p<.001$.
** $p<.005$.
*** These were 4-point scales.

A significant difference ($p<.001$) between the two groups in the number of years of schooling was found (see table 2). The heroin-dependent group had a mean of less than high school and the control group a mean of more than one year of college. The reasons for the difference were not obtained.

The work records also revealed a significant difference ($p<.001$) in favor of the control group. This confirms previous findings (11, 14, 16, 20, 21) that correlated inability to obtain and keep employment with heroin dependence. Despite their significantly poorer work record only a small minority of the heroin-dependent men in our study described themselves as unsatisfied with their work, their relationship to their supervisor, or with the military service. The skills required for the work are diverse, but regularity, ability to accept supervision, and dependability are prominent requirements for most military support positions such as these men filled. We know that these are the attributes which caused difficulties at work for many of these men. However, several of the heroin-dependent men had excellent work records.

Confirming previous studies (5, 11, 22, 23), our data indicated that the heroin-dependent men as a group were of average intelligence. However, there was a significant difference ($p<.005$) from the control group, whose mean

TABLE 3
Drugs Used by Heroin-Dependent Subjects (N=25) and Control Subjects (N=50)

Drug Used	Percents of Subjects Who Used Drug			
	Before Going to Thailand		In Thailand	
	Heroin-Dependent Group	Control Group	Heroin-Dependent Group	Control Group
Marijuana	60	52	80	56
Barbiturates	24	8	28	2
Amphetamines	28	22	28	18
Alcohol	56	80	44	66

TABLE 4
Variables Suggesting Distance from Father in Heroin-Dependent Subjects (N=25) and Control Subjects (N=50)

Variable	Positive Responses, in Percents	
	Heroin-Dependent Group	Control Group
Father's occupation unknown	12	6
Father's educational level unknown	20	12
Subject described self as other than close to father	56	42
Parents were divorced: subject lived with mother or in an institution	16	12
Father died before subject was 17	12	8

IQ was 10 points higher. This finding, combined with the fewer years of schooling and the poorer work record of this group, suggests that the heroin-dependent group had less ability to deal with the problems of living.

Previous studies (5, 10, 11, 14, 24) have also reported the prominence of broken homes, strong attachment to the mother, and the absence of a strong father among heroin addicts. We found no significant difference in the frequency of broken homes (growing up with other than both the natural mother and father). The other studies may have used subjects from disintegrated communities. Perhaps this would partially explain their finding a predominance of broken homes among addicts. No such relationship is indicated by our data.

In our questionnaire, the subjects indicated degree of closeness to each parent by choosing close, indifferent, distant, or never knew him/her. Close=4 points, indifferent=3 points, etc. No significant differences were found. Although closeness to the mother did not differ in both groups, more heroin-dependent men described themselves as something other than close to their father. Questions regarding parental fighting, divorce, excessive use of drugs and alcohol in the home, and death of parents revealed no significant differences.

Drug Use History

The heroin-dependent group had used a significant number of drugs other than heroin before leaving the United States (see table 3). Using as a criterion a list of 14 drugs that included amphetamines, hallucinogens, barbiturates, alcohol, and opiates, the difference in drug use before leaving the United States between the groups was significant ($p<.025$). The heroin-dependent group had used an average of 2.76 of the drugs on the list, and the control group had used 2.04.

An even greater difference in the same direction was found when this list was used to determine the drugs taken in Thailand. The heroin-dependent group had used an average of 3.44 of the drugs, and the control group had used an average of 1.46. This supports the reports of other investigators (12, 19, 25) regarding drug use by servicemen before their arrival in Southeast Asia. One of these studies (19) found that 59 percent of the heroin addicts in the sample had used "hard drugs" before going to Viet Nam; another study (25) found that 24 percent of heroin addicts used heroin before going to Viet Nam.

The relationship of heroin dependence to the use of marijuana and amphetamines is worth noting (see table 3). No significant relationship was found in our sample between previous marijuana or amphetamine use and heroin dependence. More than half of the men in the control group were using marijuana at the time of the study at least once a month; 14 percent used it daily.

Discriminating Variables

Ten variables appeared to differentiate the two groups: number of years of school completed; trouble with school or police; number of Articles 15 received; score on the work record questionnaire; IQ; coming from a city with over one million population; coming from a broken home (i.e., being reared by someone other than the natural mother or father); score on the closeness-to-father scale; father having died before subject was 17; and subject's not knowing occupation of father.

A discriminant analysis of these variables correctly identified 19 of the 25 heroin-dependent men (76 percent). Eleven of the 50 men in the control group were incorrectly identified as heroin dependent, a false positive error of 22 percent. This analysis indicates that the two groups were significantly different ($D^2=27.6$, $p<.01$, Mahalanobis D-square value).

Several variables were noted to consistently suggest a greater distance from the father in the heroin-dependent group. These data were analyzed giving one point for each of the variables (see table 4). The mean scores (1.16 for the heroin-dependent group and 0.78 for the control group) were not significantly different ($t=1.50$, $df=73$, $p<.20$) but worthy of further investigation.[1]

[1]A recent study by Schneider and associates (26) compared male drug addicts, other male psychiatric patients, and a control group. Using questions designed to indicate a distant or negative relationship with the father, these authors found significant differences between the drug addict group and the other two groups: the addicts had the highest scores for father distance.

LIBRARY

DISCUSSION

The dramatic differences between our data and those of previous studies appear to be due to the previous investigative focus on particular geographic, racial, criminal, and social groups. Patterns of drug availability, cost, and distribution probably influence the use of heroin. In Thailand, the setting for our study, drug distribution, drug cost, and legal issues made it easier for servicemen to obtain and use heroin.

Our population was drawn from both rural and urban sections of the United States and from every social and racial group. These men had employment, income, and support. Our hospital was the only evaluating agency for this population; every potential patient was referred to our agency. In this situation, a different perspective was possible in evaluating the pertinence of social and personality factors to heroin dependence.

The heroin-dependent group was found to have lower intelligence and poorer work and social skills. The difficulties in coping in these areas appear to be the primary problem for these men rather than measurable differences in particular personality patterns or psychopathology. A variety of personality styles was found in both groups; these did not give rise to differences that would clearly distinguish one group from the other.

Our clinical impressions of the heroin-dependent group were consistent with this analysis of the data. It was our impression that many of these men had gross difficulties in living and working (self-dependence, establishing relationships, etc.) even before they started to use heroin. However, some had above-average intelligence and adequate work and social skills. It was our clinical impression that the more intelligent and socially skilled heroin-dependent men had more problems with neurotic anxiety and depression. This issue requires further research.

Why the symptom choice of heroin abuse? In this situation, heroin was available, cheap, and its use was highly publicized as a major concern of the responsible authorities. It could induce tranquility and euphoria. Treatment and attention were virtually assured by its use. For some, it appeared to function as a self-destructive behavior.

These data and findings point out the need for a careful social and psychiatric evaluation of each person who presents with the symptom of heroin dependence and the need of many of these patients for long-term, supportive social rehabilitation.

APPENDIX 1

Work Record Questionnaire

The following questions were asked by the social work technician in an interview with each subject's work supervisor. A point was given for each positive answer, except for question 8, for which two points were possible. A perfect score was 10.

1. Does he get the job done?
2. Does he come to work on time?
3. Does he work until the end of the duty day?
4. Is he accepted as part of the working team?
5. Is he willing to accept extra work if necessary, i.e., to work late to complete a job?
6. Does he generally accept supervision without unreasonable complaint?
7. Would you say he qualifies for a promotion on the basis of his duty performance?
8. How is his performance in comparison with other members of the staff performing similar jobs?
   a. better
   b. about the same
   c. not as good
9. Do you think he would be capable of performing in a supervisory capacity if the situation required it?

Implications of California's New Mental Health Law

BY ALBERT H. URMER, PH.D.

The author describes the impact that implementation of California's new mental health law and of its amendments has had on the development of community mental health programs. The new legislation has acted as a catalyst to the growth of local mental health programs by providing restrictions on involuntary treatment as well as fiscal incentives for local programs. The effect of the legislation on patients has varied according to patient needs and the resources available in the community. Although problems and controversies have arisen regarding the placement of chronic patients, impact on law enforcement, and quality of care, the service delivery system developed in response to the new legislation has resulted in a greater emphasis on crisis intervention, greater visibility of direct services, and increased community awareness and concern regarding mental health. The author concludes that mental health laws can become the catalyst for major changes in the mental health services delivery system.

THE LANTERMAN-PETRIS-SHORT ACT (LPS) went into effect in California in July 1969. This legislation limits involuntary commitment to mentally disordered persons who have been observed to be dangerous to others, suicidal, or gravely disabled; places time limits on the duration of commitment; and encourages the development of community-based treatment programs by shifting the control of all state mental health funds to local communities. The legislation further modifies the commitment procedures by removing the courts from the process and placing responsibility on the psychiatrist. The result of these modifications has been a major change in both the involuntary commitment process and the public mental health services delivery system.

At the time the LPS was implemented there was great national interest in the impact of this legislation. The ENKI Research Institute received a grant from the National Institute of Mental Health to evaluate the legislation's effect on the involuntary commitment system. A major portion of this paper is based on this research, which included a study of pre- and post-LPS delivery systems, legal procedures, and state hospital utilization. The study included a cohort of 600 patients.

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Dr. Urmer is President, ENKI Research Institute, 9015 Fullbright Ave., Chatsworth, Calif. 91311, and Associate Clinical Professor, Neuropsychiatric Institute, University of California, Los Angeles, Calif.

This study was supported by grant MH-17927 from the National Institute of Mental Health.

CRITERIA FOR INVOLUNTARY COMMITMENT

LPS criteria for involuntary treatment are limited to individuals who are dangerous to others (DO), dangerous to self or suicidal (DS), or gravely disabled (GD) due to mental disorder. The legislation mandates that the qualified person requesting the potential patient's admission must have observed the behavior which led to the conclusion that the potential patient was DO, DS, or GD. Clinical judgment that the patient represents a class of individuals who meet the behavioral criteria is not acceptable. Several other states have criteria similar to California's DO, DS, and GD, but California's requirement of behavior observation imposes unique limitations on the application of clinical judgment as justification for commitment.

LPS COMMITMENT PROCEDURES

LPS mandated major changes in the procedure for commitment of individuals for involuntary treatment and attempted to assure services after commitment. Analysis of the new procedures, including comparisons to pre-LPS procedures, provides considerable information regarding the dynamics of the delivery system. The basic components of the delivery system affected by LPS are outlined below.

Court Petition for Commitment

The pre-LPS procedure, which is prevalent in most states at the present time, was to file a petition with the court requesting that the potential patient be committed for evaluation because of a belief that the potential patient was mentally disordered. This petition usually required medical certification but not necessarily by a psychiatrist.

LPS modifies the procedure by requiring screening in the individual's home by an interdisciplinary team before action can be taken on the petition. If the team believes that the potential patient meets the legal requirements (DO, DS, GD) and that the only feasible procedure is involuntary hospitalization, this recommendation is forwarded to the court. The court then orders the individual into the hospital for a 72-hour evaluation. Simply being psychotic and requiring treatment is thus no longer a legal ground for involuntary commitment.

The result of this modification has been a 99 percent decrease in the number of petitions for involuntary commitment filed with the courts. The dynamics behind this reduction are directly related to the jeopardy that family members perceive in the new process. Before enactment of LPS, a family member could have a medical certifica-

tion signed by a family physician filed with the court. The potential patient would then be picked up by law enforcement officers without knowing beforehand that a petition had been filed. If the potential patient was severely disordered, the probability was high that he would be committed for an indefinite period of time without ever leaving the custody of the mental health system. Under LPS, the person who files the petition becomes visible to the potential patient during the prepetition screening; potential petitioners find this jeopardy intolerable.

Emergency Admission

Both before and after LPS, mental health legislation in California contained a provision that a mentally disordered person could be transported to an inpatient facility for evaluation and treatment. The major change effected by LPS is in the restriction of who can request the admission, i.e., only peace officers and specifically designated mental health professionals. The legislation also clearly defines the conditions and evidence needed to admit the individual: generally, the referring individual must have observed behavior that leads him to believe that the mentally disordered person is DO, DS, or GD. Bizarre behavior and apparent need of treatment are not sufficient reasons.

LPS has not had a significant impact on emergency procedures, although the clearly defined language has reduced the number of admissions of mentally disordered individuals who were admitted through the petition process before the enactment of LPS. These individuals are now admitted through the emergency procedure. This change is due to the reduction in the number of petitions, so that the individual remains in the community until he is in crisis.

Extended Treatment and Duration Limits

One of the major innovations of LPS is the imposition of time limits on the duration of involuntary treatment. An individual admitted for evaluation must be released after 72 hours. If he is not released, a psychiatrist has to certify in writing that the individual requires further treatment. Court intervention is not required at this time. If the certification is issued, the individual can be detained for involuntary treatment for an additional 14 days. This is a major departure from pre-LPS procedures as well as those prevalent in most other states, which call for court intervention at the end of the 72-hour period. With LPS, there are different procedures to be applied to DO, DS, or GD admissions at the end of the 14-day period.

If an individual is admitted as DO, there are two options—release or, if the individual is still dangerous based on observable evidence, a request can be filed with the court for postcertification for an additional 90-day period. Postcertification is an adversary procedure that requires testimony and evidence that the individual is dangerous and requires further treatment. This request must be filed no later than the 12th day of the certification period so that a court hearing can be held on the 14th day. If the postcertification request has not been granted before the 14-day time limit, the individual has to be released.

If an individual is admitted as DS, a psychiatrist can certify him for an additional 14-day period of involuntary treatment without any court intervention. At the end of the 28-day period, all patients who were admitted as suicidal have to be released.

If an individual is admitted and certified as GD, the treatment facility can petition the court to have a conservator appointed for the individual after the 14-day period. This is an adversary procedure; if a conservator is appointed, he has complete power over the patient for a one-year period. Conservatorships are renewable at the end of the one-year period through a repeat of the court procedure.

The time limit on duration of treatment and the changes in the procedures have had a minimal impact on treatment effectiveness and on the safety of the community. The mandated release of DO or DS patients has not increased the rate of violence or suicide by discharged patients in comparison with pre-LPS rates.

The 90-day postcertification procedure is seldom used. The primary reason given by psychiatrists for this fact is the difficulty of testifying in court and providing evidence of the patient's dangerousness. While this reason appears plausible, it is based on the inability of professionals in public institutions to become sufficiently familiar with the patient to make a valid prediction of the patient's future behavior. The professionals are unwilling to expose themselves to the cross-examination of the adversary procedure, which requires that clinical judgment be supported by factual evidence.

The conservatorship procedure has not had a major impact on placement or treatment of chronically disabled individuals except that the change to community programs has generally resulted in the placement of individuals in inadequate community facilities rather than in state hospitals. Individuals who were long-term patients in state hospitals are now long-term patients in local board-and-care facilities. Treatment for these patients continues to be lacking.

The mandatory reduction of the duration of involuntary treatment has had a major impact on the duration of treatment for both voluntary and involuntary patients. In the first two years after the enactment of LPS the average treatment duration of involuntary patients dropped from 180 days to 15 days, while the average duration for voluntary patients dropped from 75 to 23 days. The reduction in involuntary patient treatment duration was expected because of the legal restrictions, but the influence of the rapid discharge philosophy, which permeated inpatient facilities, carried over and reduced the duration of voluntary treatment.

IMPACT ON LOCAL PROGRAMS

Before the enactment of LPS, state funds were paid for the total cost of patients in state hospitals and for 25 percent of the cost of local programs. The desire to isolate

the mentally disordered in state hospitals was therefore fiscally rewarding to the community. By changing this pattern, LPS became a major catalyst in the development of community mental health programs. LPS places all funds for mental health programs under the control of local communities. The total cost of mental health services is shared on a 90 percent state/10 percent local basis, independent of the location of treatment. Inpatients in state hospitals and outpatients in the local community are reimbursed on the same basis. As a result, the percentage of money spent on local programs increased from 32 percent to 74 percent of all mental health funds in the first three years of LPS. Concomitant with the increase in outpatient and day-care services, there was a significant reduction in inpatient services.

The increase in outpatient services appears to have had an unanticipated impact on a new group of clients who had not previously used public mental health services and who were never in jeopardy of involuntary commitment. The legislation intended that the local programs would divert individuals who were high risks for hospitalization, not that it would reach a new group of clients. A significant portion of the potential target population is not being reached by the local programs for many reasons.

IMPLICATIONS OF LPS

The broad-based implications of LPS are not necessarily reflected in the empirical findings summarized here. Some of these implications are of critical importance to states that may be considering the development of similar legislation and to the attitudes of professionals toward the mental health delivery system. While the experience in California has not provided solutions, it has identified issues which require resolution and upon which experimental work should be focused.

It appears that there is relatively little correlation between treatment duration and treatment outcome. The procedures for delivery of mental health services as an integrated system must be reevaluated; the components necessary for continuity of care must be clearly defined. There is some evidence (1) that inpatient services need to be utilized only during crisis intervention, when isolation from the environment is mandatory. We have also found (1) that the duration of inpatient treatment should be minimal, rarely exceeding five days. However, it is important that the treatment component be continuous and not necessarily tied to the domicile of the patient.

Mental health professionals must begin to separate treatment from the place of domicile; involuntary treatment and hospitalization are not synonymous. We must focus on the total milieu and consider the patient as only one aspect. With a global approach we will start considering which aspect to focus our energies on. In some cases environmental manipulation will be found to be a more effective treatment modality than modification of the patient's response to the environment.

The ENKI study (1) also found very little correlation between professional prediction of behavior and actual behavior. Therefore, an extension of the duration of involuntary treatment cannot be justified on the grounds that it will reduce future violence or suicides. It was the need to ensure that a patient would not be violent that resulted in the relatively long commitments before LPS. The staff had to be confident that the patient would not be dangerous. The professionals' uncertainty regarding their predictive abilities resulted in an unwillingness to assure society that the patient would not commit an act contrary to society's concept of its own safety and that of the patient. The result was indefinite commitment.

LPS reversed this process by requiring evidence of dangerousness; this resulted in the rapid discharge of patients. The dilemma of prediction arises because the public mental health delivery system does not provide sufficient contact between the professional and the patient to permit familiarity with the patient and his reactions to environmental stress. Prognosis is therefore poor, and society condones the incarceration under the guise of protecting itself or the patient. Even with sufficient contact and understanding of the patient's dynamics, one is still faced with the problem of controlling the environmental conditions that might lead to undesirable behavior in the patient who is adversely stimulated.

Experience with California's new law has also shown that the mental health system is frequently used to house socially incompetent individuals and that alternative systems are developed when this system becomes unavailable. For example, a significant proportion of individuals had been committed to state hospitals before LPS not because they were violent or suicidal but because of their bizarre behavior and because they were a nuisance to society; this was coupled with society's traditional fear. Since LPS, these individuals have been ineligible for commitment, but now their behavior comes to the attention of law enforcement agencies; they are therefore placed in jail.

Although the duration of their incarceration under the penal system is short, such individuals recycle frequently. We feel that this problem has developed because neither society nor mental health professionals have been willing to accept the reality that the mental health system had been used as a convenient resource to isolate the socially incompetent. Little preparation has been made for the influx of this group into society. We have to accept the fact that this group needs both protective care and assistance in daily living.

A less obvious but still important change brought about by LPS is the elimination of the role of the court in the early commitment process and the placement of responsibility on the psychiatrist. Evaluation of this procedure has shown that it is effective and results in a more critical evaluation of the need for commitment. One could have anticipated this result because the pre-LPS commitment process divided the actual responsibility. Psychologically, neither profession had to accept the ultimate responsibility for the commitment. LPS legislation places that responsibility on the physician, who, after all, makes the ultimate recommendation on which the courts should base their judgment.

LPS has also shown that a rapid and unplanned shift of funds from the state hospital system to community-based programs does not necessarily result in the development of effective precare or aftercare programs as alternatives to hospitalization. It is important that legislative goals be clearly defined and that effectiveness criteria be included in the legislation.

RECOMMENDATIONS

The study of the impact of LPS has led to some basic recommendations for consideration by state legislatures and the mental health profession.

1. The issues of involuntary treatment and inpatient services must be separated. There is very little evidence that involuntary treatment in a confined setting is more effective than other modalities in other settings. Incarceration should be limited to situations where the patient has to be removed from his environment for therapeutic considerations, society's safety, or his own safety.
2. Public mental health delivery systems must increase their consideration of the total environmental structure and deal with the patient as an integral part of it rather than as an isolated organism in a psychological void. The greatest potential for effective intervention is through a global approach to treatment.
3. Legislatures should place more emphasis in their legislation on development of policies than on detailed treatment procedures. Before this change can occur, the mental health profession must convince legislative bodies that they have the skills to implement the policies and that as a profession they will attempt to meet legislative goals.

APA Grant Program for Minority-Group Medical Students and Residents

A small number of qualified minority applicants (including but not limited to American Indians, Asian Americans, black Americans, and Spanish-speaking Americans) will receive residency stipends, assistance in selecting a residency program, expenses to a yearly meeting with other minority fellows to share experiences and administrative help through APA's Office of Minority Affairs. The program is sponsored by APA, with funds provided by the National Institute of Mental Health.

Applications are being accepted through March 15, 1975, for residencies beginning in July 1975; after that date applicants will be considered for subsequent years. Applicants must be U.S. citizens and must have graduated from a U.S. medical school or possess the ECFMG certificate.

For further information write Jeanne Spurlock, M.D., Office of Minority Affairs, American Psychiatric Association, 1700 18th Street, N.W., Washington, D.C. 20009, or call (202) 232-7878.

Evaluation of a Regional Indian Alcohol Program

BY LAWRENCE G. WILSON, M.D., AND JAMES H. SHORE, M.D.

The authors analyzed follow-up data collected by an Indian counselor and a psychiatrist on 83 American Indian alcoholic men. Follow-up status was judged by an interdisciplinary panel according to a six-step rating scale. The 44 percent improvement rate compares favorably with other treatment programs, especially in view of the selection process, which favored difficult patients. The authors suggest that the interdisciplinary rating panel is an approach that can prevent erroneous judgments of the drinking status of American Indians.

THE RAPID GROWTH of alcohol treatment programs for American Indians within the past three years has created the need for a systematic evaluation approach. This paper reports a follow-up evaluation of 83 American Indian alcoholic men from five major Northwest tribes who were treated in a regional intertribal and interagency alcohol rehabilitation program. Their follow-up status was assessed at an average of 18 months after inpatient discharge.

The purposes of the research were as follows: 1) to develop a method of assessing the follow-up status of Indian alcoholics; 2) to identify the characteristics of Northwest Indian drinkers who had been treated in this program; 3) to analyze the follow-up status data for differences between tribal groups and differences on demographic, social, and health variables; and 4) to compare these data with results from other American Indian alcohol treatment programs.

ALCOHOL TREATMENT FOR AMERICAN INDIANS

Alcoholism as a major health problem of American Indians has been widely discussed by both Indian and non-Indian sources (1). Many theories and viewpoints that attempt to explain the extent of drinking in Indian populations have been reported in the anthropological and sociological literature in past years. However, the earliest report on the effectiveness of alcohol rehabilitation programs for Indian people appeared in the literature in 1968. Ferguson (2) and Savard (3) reported on separate projects that evaluated the outcome of treatment with disulfiram in Navajo communities. Their reports described the therapeutic effect of disulfiram positively and recommended its continued use. Shore and Von Fumetti (4) reported on three tribally sponsored alcohol programs, emphasizing four factors: 1) the involvement of Indian people in planning and operating their own programs; 2) the treatment philosophy that had evolved within the context of the Indian communities; 3) the relationship of the court to these programs; and 4) the need for uniform standards to evaluate patients.

The regional alcohol rehabilitation program described in this paper is located in the Pacific Northwest, which includes the states of Washington, Oregon, and Idaho. The treatment service was coordinated by the Mental Health Program of the Indian Health Service and was a joint effort by tribal alcohol programs, the Indian Health Service, and a private inpatient treatment center.

Northwest Indian Tribal Programs

Indian tribes of the Pacific Northwest consist of 33 diverse and geographically isolated groups with two distinct cultural backgrounds, the Northwest coastal and plateau cultures. The large number of tribes and the absence of Indian hospitals necessitated sharing of the inpatient services for alcohol treatment.

All tribes were included in the coordinated rehabilitation service. Five tribal alcohol programs from four plateau tribes and one coastal tribe were invited to participate in the evaluation of this program. These tribes were selected because of their larger populations and their established reservation-based alcohol rehabilitation programs. Since 1969, these five programs had worked cooperatively with the Indian Health Service to establish the regional treatment center.

The reservation-based tribal alcohol programs are totally outpatient in design. They receive funding support from the National Institute of Alcohol Abuse and Alcoholism through their tribal governments. Mental health consultation is available through the Mental Health Branch of the Indian Health Service, a regional consultation service. A third component of the coordinated treatment program is a private residential treatment center for male problem drinkers that is located on a major Northwest Indian reservation. The inpatient program

At the time this work was done, Dr. Wilson was a resident in psychiatry at the University of Washington School of Medicine, Seattle, Wash., where he is now Instructor, Department of Psychiatry and Behavioral Sciences. He is also Staff Psychiatrist, Veterans Administration Hospital, 4435 Beacon Ave. South, Seattle, Wash. 98108. Dr. Shore was Chief, Mental Health Office, Portland Area Indian Health Service, Portland, Ore., when this work was done; he is now Director, Community Psychiatry Training Program, and Associate Professor of Psychiatry, University of Oregon School of Medicine, Portland, Ore.

The authors wish to gratefully acknowledge the aid of Ms. Carolyn Dearborn, Program Assistant, Mental Health Office, Portland Area Indian Health Service.

consists of a standardized regimen of group and individual counseling and an intensive alcohol education program. Within this general program, a special treatment plan was developed for Indian patients that includes regularly scheduled sessions with Indian counselors and outpatient follow-up on the home reservation. The coordinated treatment aspects of this rehabilitation program include case identification by the local tribe alcohol program (usually by an Indian alcohol counselor), referral through the Indian Health Service to the regional inpatient center, including evaluation of physical status and special psychiatric examination where indicated, and coordinated follow-up after discharge by each of the tribal programs and the Indian Health Service. Thus, the treatment program is regional in scope, intertribal in nature, and interagency in operation.

METHOD

The study sample consisted of 83 Indian men from the Colville, Spokane, Warm Springs, Yakima, and Lummi tribes. All tribes were of the plateau culture except the Lummi, who are a coastal tribe. These five tribes consist of approximately 15,000 reservation Indians, 60 percent of the region's reservation Indian population. Eight additional tribes were represented by 1 individual each. The sample included all Indian men referred to the regional inpatient treatment center during an 18-month period from January 1971 through June 1972. Since this was the beginning of the regional treatment program, Indian women were being referred in smaller numbers and were not included in the study sample.

Information was collected systematically by the Indian alcohol counselor for each subject. This included demographic data, education and employment background, arrest record, and health history. The data were compiled from existing case records and personal interviews. Health histories were gathered by the project psychiatrist through a review of medical records. A profile was developed on each subject that was used as the data base to assess follow-up status.

Subsequently, a rating panel met on each reservation to determine the follow-up status of all individual patients. The project psychiatrist (LGW) met with an Indian alcohol counselor from the local tribal program and a psychiatric social worker who was also working in the local Indian community. This three-member panel employed a six-step rating scale patterned after that developed by Fitzgerald and associates (5). The rating was specifically aimed at defining the patient's status in areas of personal, family, and community functioning in relationship to his current drinking pattern and emotional adjustment. All information from the profile of individual patients was shared with the panel, as well as current information about the patient's functioning, which was usually supplied by the Indian alcohol counselor. Anecdotal information from friends, relatives, or other knowledgeable community people was included. Each patient (and his spouse, if applicable) was rated separately by each of the three panel members. After separate ratings, a group consensus rating was given, which was used in the final analysis. There was a high degree of interrater agreement, which indicated that the Indian alcohol counselor and the project psychiatrist agreed about patient ratings.

RESULTS

Demographic Data

The average age of the subjects was 41 years, with a range of 21 to 67 years. Indian men in their 30s and 40s were most heavily represented (N=25 and 24, respectively). Subjects in their 20s (N=12) were underrepresented in comparison to an epidemiological pattern of an entire Northwest tribal population (6). Twenty-two of the men were married and 61 were unmarried. Educational experience ranged from the fourth grade to two years of college, with the average being a ninth-grade education. Forty-nine subjects were employed, either full-time or part-time, and 34 were unemployed. Of the 83 subjects, 40 had had military service. There was a representative sample of religious affiliation throughout the group, with 41 Catholics, 12 Protestants, and 11 members of the traditional Indian religion.

The majority of the subjects did not fit the stereotype of highly mobile "skid-row" alcoholics: 68 of the 83 were living on reservations, and 45 had lived in their present home for more than one year. Using the two-factor social class index of Hollingshead and Redlich (7), distribution was predominantly in Classes IV (N=9) and V (N=55). In a further refinement, an Indian social class rating was assigned, using the method of Shore and associates (6).[1] With this technique, there was 1 subject in Indian Social Class I, 28 in Class II, and 36 in Class III (unknown=18). Since the ratio of these classes was 1:2:1 in a representative sample of one total Northwest tribal population (6), our sample is significantly overrepresented in Class III. In the epidemiology pattern for one tribe, alcoholism was more evenly spread through the classes, although the most severely impaired alcoholics were from Class III.

A history of arrest records, obtained for 64 of the 83 subjects, indicated that 8 subjects had had no arrests, while 56 had one or more. There was no previous treatment history in 24 of the 83 subjects; 29 listed one or more prior rehabilitation programs. Of the 68 subjects who answered a question assessing their own medical status, 34 judged themselves to have good or excellent health, while 34 considered themselves to be in fair or poor health. Fifty-two individuals reported one or more hospitalizations, usually related to alcoholism; 16 subjects were admitted a second time to the inpatient center and 2 subjects had three inpatient admissions. Many sub-

[1]Since most reservation Indians fall into the lowest Hollingshead-Redlich categories, Shore and associates (6) divided the Indian population into three main modal distributions of Hollingshead-Redlich scores. This gave a distribution they called "Indian Social Class," thought to be a truer description of the social stratification of Indian communities.

TABLE 1
Follow-Up Status of 83 Indian Alcoholics

Rating*	Number
Clear improvement	
1. Complete abstinence in past year or since discharge from treatment facility and maintaining vocational, home, and family responsibilities.	11
2. Occasional or sporadic drinking in past year or since discharge, but maintaining vocational, home, and family responsibilities.	12
Erratic improvement	
3. Drinking periodically or regularly during past year or since discharge, but no outstanding community problems or severe effects on home and family.	13
No improvement	
4. Drinking to the extent that vocational and family responsibilities are not maintained—has come to the attention of the community for drinking in the past year or since discharge.	35
Lost to follow-up	
5. Drinking status unknown.	10
6. Deceased.	2

*Based on the classification system used by Fitzgerald and associates (5).

jects in the group had experienced severe alcoholic withdrawal, but the medical records were not complete enough for a statistical analysis. Disulfiram played a minor role in the follow-up treatment plans of this group in spite of the positive results previously reported with Navajo alcoholics.

Follow-Up Status

In order to summarize follow-up status and compare the results with the outcome of other treatment programs, categories 1 and 2 of the six-step classification (see table 1) are considered to be clear improvement, category 3 represents erratic improvement, and category 4 indicates no improvement. Categories 5 and 6 indicate loss to follow-up. Clear improvement was demonstrated in 28 percent of the subjects (N=23), erratic improvement in 16 percent (N=13), and no improvement in 42 percent (N=35). Twelve subjects were lost to follow-up. Thus, some improvement was seen in 44 percent of the patients and no improvement in 42 percent at follow-up.

Follow-up status was then compared to specific characteristics in the profile of the Indian alcoholic. There were no significant differences in follow-up status between the five major tribal groups or between decade of life, type of marriage (intra-, inter-, or extratribal), type of religion, or Indian social class (which includes scores for type of employment and level of educational attainment). Several comparisons deserve special comment. We observed a decreasing proportion of patients remaining in the "clearly improved" category with increasing time lapses since discharge from the inpatient facility. Sixty-six percent of those who had been discharged less than 12 months previously were clearly improved, as compared with only 26 percent of the patients who had been out longer than 12 months. Follow-up status and a history of no arrests were positively correlated—6 of the 8 subjects who had a history of no arrest showed significant improvement. However, the reverse was not true, i.e., those subjects with a history of multiple arrests did not necessarily receive poor follow-up status ratings—8 out of 29 subjects with four or more arrests showed clear improvement at follow-up, 5 had erratic improvement, and 16 showed no improvement. Also, the lack of a significant relationship between follow-up status and religious affiliation did not substantiate earlier impressions of many counselors, who hypothesized a positive relationship between treatment outcome and traditional Indian religion. Instead, there was a trend for Protestant subjects to show greater improvement at the time of follow-up ($.05<p<.10$). Eight out of 11 Protestants showed improvement (clear or erratic), while only 2 were considered to have shown no improvement.

Married subjects had a significantly higher improvement rating than those who were unmarried (i.e., single, separated, divorced, or widowed) ($\chi^2=10.88$, $p=.005$). Less than 20 percent of the married subjects were unimproved, while over half of the unmarried subjects were unimproved. Drinking status of wives was known for 16 of the married subjects, and the man/wife drinking status was a direct one-to-one relationship for 10 of these couples.

In the group of 18 subjects who were readmitted for two (N=16) or three (N=2) inpatient treatment sessions, 8 showed improvement, 7 showed no improvement, and 3 were lost to follow-up.

DISCUSSION

Since the components of this regional Indian alcohol program include inpatient treatment and geographically distant follow-up resources, a documented improvement of 44 percent at an average of 18 months after discharge from inpatient care compares favorably with other treatment programs. Shore and Von Fumetti (4) reported improvement ratings of 56 percent (28 percent clear and 28 percent erratic improvement) for 642 Indian alcoholic patients treated in three tribal programs. However, these were outpatient programs, and it is likely that referrals to the program we have described were selected from the more difficult cases in each counselor's outpatient caseload. This would also account for the overrepresentation

of subjects from Indian Social Class III in the treated population and would indicate that the most socially disadvantaged drinker did have access to the program.

There was no evidence from our study to support Ferguson's (2) conclusions that older, more traditional Indian men benefit most from an alcohol treatment program. However, Ferguson was working with Navajo rather than Northwest Indian tribes and with a program that strongly emphasized disulfiram. There was no significant difference in response to treatment among different age groups in the Northwest program, but the underrepresentation of subjects in their 20s points to an exclusion of the younger Indian alcoholic from this patient sample. Perhaps an alcohol program with an inpatient component is not an appropriate resource for the young Northwest Indian male. It is also possible that the case-finding approach favors older men with more obvious signs of severe alcoholism.

The problems encountered in the collection of data and in the coordination of diverse resources in this program were enormous. For example, in the review of medical records, an alcohol problem was identified for 89 percent of all subjects, but a definite follow-up plan for alcoholism was recorded on only 23 percent of these charts. The data were available in the local Indian community, but it was only with great effort that all sources were brought together. Levy and Kunitz (8) have commented that

> the numerous difficulties which have plagued the data gathering process in studies of American Indian drinking, while they remain with us, may be overcome to a great extent by the use of more uniform methods of investigation, explicit definitions, and whenever possible, by a multidisciplinary approach. As long as the methods of one discipline remain unchecked by the use of other methods, erroneous interpretation of the findings will be unnecessarily frequent. (p. 25)

The interdisciplinary rating panel described in this study is an approach that provides a check for erroneous judgments of Indian drinking status. Perhaps with broader acceptance of uniform evaluation standards, systematic inquiry into the effectiveness of Indian alcohol programs can lead toward a solution of the major health problem of American Indians.

The Future Educational Needs of Psychiatrists

BY ROY R. GRINKER, SR., M.D.

The author states that psychiatry must work at defining its boundaries as a discipline before the question of how to educate future practitioners can be answered. The medical student is presented with a bewildering array of approaches to psychiatric treatment and is pressured to choose quickly. The author calls for collaboration among the various parts of psychiatry—social psychiatry, community psychiatry, research, biochemistry, etc.—with other university faculties such as the humanities and basic sciences. The goal of this collaboration would be to produce a mature professional capable of dealing with the whole person. He also calls for a greater emphasis on research to equip psychiatry with the necessary knowledge to establish its role in our ever-changing contemporary society.

IMPLIED IN THE TITLE of this paper are questions that can no longer be answered by psychiatrists because our discipline has lost its boundaries. Psychiatry has been incorporated and defined by the social systems of the human consumer and regulated by superimposed governmental bureaucratic controls. How then can we answer the questions of the future for which we should be educating psychiatrists?

Perhaps we do not differ much from other service and scientific endeavors as we view the attempts to predict what changes will occur in the rapidly approaching next century. Indeed, a new, supposedly scientific discipline called "futurology" is engaged in the game of betting on what comes next. As far as I can tell, a succinct statement of the conclusions of this discipline is, "More of and better than."

So much of what has happened in the last decade denies the future psychiatrist an opportunity to mature. If a psychiatrist needs any one quality, it consists of a high level of maturity achieved through being exposed to a wide variety of life experiences. The psychiatrist should have the experiences of suffering, succeeding, and losing his adolescent narcissistic self-evaluation and his grandiose idealism. Only by attaining his own lifestyle and a stable self-system is he able to help others within a mutually trusting and respecting therapeutic alliance.

HURRYING MEDICAL EDUCATION

There is now a mad rush to hurry medical education. It has been shortened to three years, and more and more time has been given over to electives for students who are not able to choose. The abolishment of the internship and the direct promotion to residency means that specialty education has to be chosen, applied for, and accepted even before the full round of clerkships has been experienced. No wonder the medical student is confused and the first-year resident's syndrome of anxiety and depression is worsened. It is interesting to hear how these youngsters choose their future discipline—by means of advice from others rather than through their own motivation. Their exposure to psychiatry in medical schools is brief and irrelevant. They apply for a strange mixture of residencies.

The internship functions not only to increase the student's knowledge but, more important, to increase his capacity to deal adequately with other human beings and to become professionalized. Fortunately, at Michael Reese Medical Center we have always started our residents on

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Dr. Grinker is Director, Institute for Psychosomatic and Psychiatric Research and Training, Michael Reese Medical Center, Chicago, Ill. 60616, and Professor of Psychiatry, Pritzker School of Medicine, University of Chicago, Chicago, Ill.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editors consider this material to constitute a comprehensive analysis of the topic.

October 1 so that all of the staff are back from their summer vacations and available for preliminary orientation. We now insist that between graduation in June and starting the residency in October the students take a mini-internship in medicine, pediatrics, or neurology.

Probably the best evidence for the deficiencies in psychiatric education in medical schools is the experience of our liaison psychiatrists who work on the medical and surgical wards. Over the last 30 years the house officers from medical schools all over the country have become more knowledgeable about organs and organ systems, but they are still woefully deficient in their grasp of illness-related problems, conflicts, interpersonal difficulties, and emotional fluctuations in the whole person. Yet some of these house officers aspire to go into family medicine!

Turning back to the psychiatric resident who is confronted at the beginning of his career with a system fragmented into parts belonging to what we as teachers recognize as psychiatry, I need only mention the various forms of treatment, the specialized peer group programs, and the multidisciplinary aspects of research. To become a general psychiatrist the resident has to taste these various parts all too briefly during his first two years of residency (1). Then he may elect one part of the specialty of psychiatry for a special track during his third year.

MEDICAL OR SOCIAL PSYCHIATRY

There has been a peculiar debate during the last several years between those psychiatrists and clinical psychologists advocating the medical model of psychiatry and those adhering to a so-called social model. I consider this dichotomy one of the worst possible examples of dualistic thinking. Complementarity instead of separation has been and is the goal of most psychiatrists. However, to ensure our concern with more than the internal subjective complaints of our patients and their social behavioral incompetence, we need to know and teach our students the components of the medical model to extend their focus beyond interpretative explanations.

This means a knowledge of diagnostic categories and the current nosological classification; a knowledge of biogenetic and organic structural and chemical dysfunctions; a knowledge of psychopharmacology and at least the rudiments of biochemistry; and a familiarity with characteristics, predispositions, and approaches to diseases of development and regression in various age groups. The psychiatrist must be a doctor; he must demonstrate in practice that he is not forbidden to look at or touch the body even though his main interest is in mental disturbances.

Unfortunately, the future psychiatrist hears from his teachers (who must conform to the demands of governmental funding agencies that the student be encouraged to do community psychiatry) about a nonsystem planned for primary prevention—an illusion worthy only of bureaucrats. The new psychiatrist cannot be a public health physician, a sociologist, or a social engineer to alter the horrible socioeconomic predispositions to the more serious mental illnesses.

The workers in the field know that the "psychiatrization of life," as defined by Cerrolaza (2), is a by-product of illusory thinking. The psychiatrist makes a poor politician when working with community lay boards who have been appointed according to mandate. The boomerang of all these "promises, promises," to borrow the title of a recent play, is less effective psychiatric care and more disorganization and confusion in the field.

Stemming not from the community mental health movement but from psychiatrists who are currently engaged in private practice is the mixture of private practice with part-time paid jobs in institutions and in-hospital services dedicated to caring for the indigent or the working poor. There is no sharp separation of those who deal with the public or the private sector; doctors who work in the public sector universally moonlight in private practice.

Although the individual psychiatrist, with some exceptions, is not politically astute, psychiatric organizations have become increasingly political. Scientific sessions are often replaced by policy discussions in an effort to defend psychiatry against the controls, restrictions, and demands of the government; to contest impoundment of funds; or to issue late position papers on issues affecting the mental health of our citizens. But the political psychiatrist has been unfamiliar with the systems aspects of the parts of psychiatry that seem to be in conflict.

PLURALISTIC SOCIETY AND PSYCHIATRY

Returning to the real world of psychiatry, we have a pluralistic concept of the psychiatries often so disparate and sometimes so contradictory that the psychiatrist as practitioner or scientist rides madly in all directions (3). However, he is not alone in his confusion because our society is pluralistic. It is divided into ethnic, social, and economic groups, each of which has different problems in coping with the strains of the mythical whole.

Furthermore, what we classify as diseases or at least divisions in our notoriously inaccurate and inadequate nosological classification do not remain steady. Cross-sectional studies reveal shifts in outward behaviors, in disturbances in thinking, and in inner feelings. Not only do such shifts occur in individuals but there are profound changes in diagnostic entities—from dramatic histrionic excitements to highly constricted, inhibited lifestyles. Schizophrenia just isn't what it used to be!

We have now faced the vertigo-inducing problems. Psychiatric diseases are changing, deviances in individuals shift over the individual's life span, society is changing faster than ever before, and educational facilities and methods are changing. Are we then speaking of educational needs of psychiatrists or the psychiatric needs of the public? Neither can be defined with any degree of certitude, and I would advise the beginner not to believe anyone who speaks positively about the future. Many of us have wished that we too could start again to specialize in

a new, promising, and exciting phase of psychiatry without having to consider the fact that all phases belong together as parts of the whole.

THE TIME PROBLEM IN EDUCATION

The time problem in the education of future psychiatrists is uppermost in our minds, but there has been no general solution. Some feel that the similarity of training programs produces a stereotyped result because curricula are almost identical everywhere in the country. Training programs differ only in the quality and experience of the teachers. Perhaps each institution should be identified by its major goal, but that too demands a premature decision on the part of the student. Perhaps the residency program should be extended by one or two years, just as child psychiatry includes a fourth-year fellowship. But increasing the time goes against the national trend toward shortening the time of education. Perhaps the third year should be a mobile period during which the student may finish his education at a place that offers the best special track chosen by the resident during his two years of general or eclectic experiences. This too demands sacrifices that most highly autonomous institutions are not willing to make.

The theme of the 1974 annual meeting of APA, "Man and His Cities 1974; Survival in 1984?" was unduly pessimistic in that it connoted the possible nonsurvival of psychiatry in 1984. I believe that with a sensible national health program backed by the national psychiatric, psychological, and social service organizations, care of psychiatric patients may be able to adapt to the changing times. There will always be a place for our services because collectively we belong to the only field concerned with the whole person.

RESEARCH AND CHANGE IN PSYCHIATRY

Brodie and Sabshin (4) reviewed the number and types of research articles published in *The Archives of General Psychiatry* and *The American Journal of Psychiatry* during the last decade. At the beginning of the decade there was a weak emphasis on research (37 percent of the papers). This emphasis had increased by the end of 1972 to 48 percent. Declining governmental support may reverse this trend in the next decade. In order of frequency within the biopsychosocial system, articles on biological research (genetics) were most frequent, psychological articles second, and sociological articles third. In order of kinds of topics, mechanisms (dynamics) came first, therapy (biological) second, and etiology third.

We cannot stand still and teach what either is doubtful or should be discarded. Our hope for the future rests not only in adapting to changing social systems but in creatively developing new understanding and better methods. In plain terms this means more emphasis on research. For this we need more than the kind of education for which the medical schools are solely responsible; this system has failed badly in the last several decades. We need the whole university. The faculties of the social sciences and humanities and preclinical faculties of basic sciences must become collaborators in education with appropriate clinicians in the medical school. The success of such learning experiences involves faculties willing to leave the confines of their departmental or specialty compounds and enter into a viable and effective transactional process with new sets of colleagues.

In growth and development the trend is upward from relative undifferentiation, toward differentiation, toward greater refinement in development of control mechanisms, and toward decline in old age. There are also processes that push the organism back to a more undifferentiated state. This is perhaps more easily understandable when we speak of psychological regression, but it occurs in physical regression as well. If we can get the student to recognize that there are no dichotomies between genetics and environment, no sharp differentiations between levels of development, and no independence of any phase of the life cycle, I think that we will have developed what might be called the philosophy of ontology in relation to scientific disciplines and to the therapeutic aspects of medicine (5).

The future of psychiatry hinges on changes in the shifting behaviors of man in a changing society. We cannot predict these changes at this time. For example, the wholesale increase in return of patients to the community from state mental hospitals may increase the pathogenetic biogenetic pool. Shifts in family constellations from the extended to the nuclear family, increased urbanization, changes in the kind of parenting, and other social and economic factors may result in changes in the kinds of coping available to succeeding generations.

SOCIAL CHANGE AND SOCIAL PSYCHIATRY

All of this means that psychiatry is necessarily part of the processes of social change—at least in diagnosis, treatment, and (possibly) preventive measures. All the more reason why solid, well-planned research in all of the many disciplines of psychiatry should be supported and greatly extended if our civilization is to be kept from nurturing the seeds of its own destruction. We can no longer afford the luxury of making public generalizations for narcissistic purposes. Those who treat should treat adequately the problems of difficult lives. Those who investigate should have adequate support to be free to research what needs to be researched. But these endeavors do not satisfactorily define what is popularly called social psychiatry.

Social psychiatry is a well-meaning term but completely inundated with confusion, multiple definitions, and misunderstandings. Its basic science is epidemiology, which is concerned with estimates of incidence and prevalence of mental illness. It deals with differential distribution of mental disease geographically and in various social classes. However, it is obstructed by resistance against statistics and faulty psychiatric taxonomy. Nev-

ertheless, institutions will have to document their utility some day. This is not now possible.

What so-called social psychiatry, with its politicalization of primary prevention, does is create an identity crisis in the student: he or she is seduced away from treating the individual patient. The individual is considered worthless in comparison with communities of various sizes. Social psychiatry turns away from the current explosion of research in biological psychiatry. It obstructs our striving toward a modern neuropsychiatry. Social factors must be added to any formulation in psychiatry, but not as goals in themselves.

To repeat the statement in the first sentence of this paper, our discipline has lost its boundaries. If we plan to educate therapists and investigators we need to redefine our system of a biopsychosocial conglomerate in order to educate wisely for the future. If we fail in this task we face what Bertrand Russell (6) stated so pessimistically:

> The near future must be either much better or much worse than the past. Which it is to be I do not know, but those of you who are still young will know before very long. (p. 64)

Emotional Problems of Residents in Psychiatry

BY MAJ. ANDREW T. RUSSELL, MC, USA, ROBERT O. PASNAU, M.D., AND ZEBULON C. TAINTOR, M.D.

The authors used a questionnaire technique to determine the magnitude of the problem of emotional illness and poor performance during psychiatric residency, the procedures that are used to screen for or help disturbed residents, and characteristics that differentiate residents who are at risk. The data indicated that residents who have problems that lead to termination are rarely free of emotional disturbance. The general belief that women, foreign medical graduates, and minority group members are at higher risk for problems during residency was not supported; however, younger residents and transfers from other programs appeared to be at risk. A disturbing finding was the high rate of suicide reported. The authors stress the need for further work with the "marginal" resident and for research on screening and supportive procedures.

THE PSYCHIATRIC LITERATURE in recent years has reflected a growing concern with the subject of emotional illness among psychiatrists during their training years. In 1962 Halleck and Woods (1) pointed out the lack of reliable statistics on the causes of failure in residency training programs. In what is now considered a classic study of psychiatric residents, Holt and Luborsky (2) emphasized the changes that take place as the resident undergoes a maturational process which leads to the emergence of a new adult identity. Pasnau and Bayley (3) reported an increase in depression among first-year psychiatric residents, as measured by the Minnesota Multiphasic Personality Inventory (MMPI). Duffy and Litin (4, 5) looked extensively at the emotional problems of physicians and the relationship of these problems to the training period. They emphasized the importance of evaluation, screening, and counseling during the medical school years. The importance of such factors as family relationships, drug and alcohol abuse, the special situations faced by the woman resident, and the relation of these factors to emotional illness among physicians were also noted in these studies (4, 5). Garetz (6) examined factors that might predict success or failure among psychiatric residents and found that although some aspects of the MMPI were helpful in distinguishing outstanding from poorly functioning residents, further research on the problems of women residents and foreign medical graduates was necessary.

Kelly (7) used a questionnaire technique to study the incidence of both suicide and emotional problems among psychiatric residents. He found an incidence of psychiatric disabilities of "something over four percent" in a 10-year sample. Kelly also concluded that there was a need for more careful screening of residency applicants and recommended a variety of procedures to aid the "problem" resident.

While the literature cited gives an indication of the interest that exists regarding the problem, there is a dearth of valid statistical information on the nature and scope of emotional illness among psychiatrists in their training years. Recognizing this, a task force of the American Association of Directors of Psychiatric Residency Training was formed in January 1973 to study this matter from a nationwide perspective. It is the intention of this paper to briefly summarize and discuss the findings of that task force.

METHOD

A 68-item questionnaire was designed to provide answers to three major questions: 1) What is the magnitude of the problem? 2) Are there certain characteristics that

Revised version of a paper read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

At the time this work was done, Maj. Russell was a resident in psychiatry at the University of California, Los Angeles, School of Medicine. He is now with the Department of Psychiatry, Headquarters, U.S. General Leonard Wood Army Hospital, Fort Leonard Wood, Mo. 65473. Dr. Pasnau is Associate Professor of Psychiatry and Chairman, Graduate Education Committee, Department of Psychiatry, Center for the Health Sciences, University of California, Los Angeles, School of Medicine. At the time this work was done, Dr. Taintor was Director of Graduate Education in Psychiatry, State University of New York, Buffalo, N.Y. He is now Director of Multi-State Information Systems, Rockland Research Center, Orangeburg, N.Y. The authors are all members of the Task Force on Emotional Problems of Psychiatric Residents of the American Association of Directors of Psychiatric Residency Training.

This research was supported in part by the State of California Department of Mental Hygiene; the University of California, Los Angeles; the Mental Retardation Program of the Neuropsychiatric Institute of the University of California, Los Angeles; grant 927 from the Maternal and Child Health Service, Health Services Administration; and grants HD-04612, HD-00345, and HD-05615 from the National Institute of Child Health and Human Development, National Institutes of Health. Computing assistance was obtained from the Health Sciences Computing Facility of the University of California, Los Angeles, sponsored by Special Research Resources Grant RR-3 from the National Institutes of Health. Programming assistance was provided by the Mental Retardation Program Computing Resources Group.

Opinions expressed herein are those of the authors and do not necessarily reflect the views or endorsement of the Department of the Army.

The authors wish to thank the officers and members of the Task Force of the American Association of Directors of Psychiatric Residency Training for their support, the APA Division of Manpower Research and Development—Ms. Carol Nelson in particular—for assistance, and Louise Epps, Ph.D., for aid in the preparation of the statistics in this paper.

distinguish the emotionally disturbed or failing resident from his colleagues? 3) How do residency programs screen for and respond to the emotionally disturbed or poorly performing psychiatric resident? The questionnaire was designed to obtain data concerning two different groups of residents: 1) those who dropped out, were terminated, or were asked to resign; and 2) those who were able to be maintained in the program despite identified marginal or failing performance and/or severe emotional problems.

The questionnaire was mailed initially to the residency training directors of all the active psychiatric residency programs in the United States and Puerto Rico. Two follow-up mailings were then sent to programs that had not responded to the first inquiry. The mailing list was derived from *A Descriptive Directory of Psychiatric Training Programs in the United States, 1972–73* (8). Combining some programs that responded as a unit, we contacted a total of 251 programs and received 207 usable replies, a return rate of 82 percent. These 207 programs represented 3,737 first- through third-year residents in training for the academic year July 1971 to June 1972. Our sample represented 91.5 percent of the 4,085 residents in training during that period. Child psychiatry and other subspecialty trainees were not included in the survey. The types of programs that composed our sample (i.e., university, state hospital, Veterans Administration, private, etc.) did not differ significantly from the national distribution.

RESULTS

The data indicated that 6.9 percent (N=259) of the total sample of 3,737 residents did not complete the year. Of these 259 residents, 65 percent (N=167) left in good standing, 26 percent (N=68) dropped out or were terminated because of emotional illness, and 7 percent (N=19) left or were terminated primarily because of academic difficulties, with no diagnosis of emotional illness. Five residents left programs for other reasons, including unethical behavior, family demands, or "being angry, hostile, and suspicious." The small size of the groups who left for academic or miscellaneous reasons confirms our impression from experience that residents who exhibit major difficulties severe enough to lead to termination seldom do so independent of emotional disturbance.

Four residents in our survey took legal action in support of their contention that they should remain in their programs; one program reported that this step "frightened and intimidated" the residency committee.

The 68 residents who did not complete their training year due to emotional illness were placed in diagnostic categories as follows: 1) behavior or character disorder —43 percent (N=29), 2) severe neurosis or depression— 35 percent (N=24), 3) psychosis—18 percent (N=12), and 4) death by suicide—4 (3 suicides were originally reported to the survey, and 1 more was brought to our attention after the data were processed). The total of 4 suicides in the 1 year studied gives a crude suicide rate of 106/100,000. To the best of our knowledge, this is the highest rate yet reported for any residency specialty. We have discussed the implications of this disturbing finding in another communication (9).

There were 220 residents who were able to finish the academic year despite marginal performance and/or emotional illness; these represented almost 6 percent of the sample of 3,737. Both this group and the group that terminated because of emotional problems were categorized on 13 background characteristics, and the results are shown in table 1. The two groups differed in three categories—age, history of marital problems, and history of psychotherapy. This emphasizes the need for careful consideration of these three factors in evaluating applicants to residency programs. However, in spite of these differences, the basic similarity between the two groups is striking.

When the results for the combined group of 288 problem residents (those who dropped out because of emotional problems or stayed despite problems) are compared with the few national statistics that are available for the residency population as a whole (10), some interesting observations can be made. In 1971–1972, 27 percent of the national psychiatric residency population consisted of foreign medical graduates. This figure does not differ significantly from the proportion of foreign medical graduates in our problem group (24 percent). Similarly, women constituted 15 percent of the general residency population, which is not significantly different from the proportion in our sample of problem residents (17 percent). Although no current data are available concerning minority group residents, an American Psychiatric Association survey in 1969 (11) found that 24 percent of the psychiatric residency population were members of ethnic minority groups. This compares with a figure of 16 percent for the problem group in our survey. If one assumes a similar national figure for 1971–1972, members of ethnic minorities had a significantly lower incidence of marginal performance and/or emotional difficulties than would be expected by their distribution in the total residency population ($p<.01$). Thus, our results do not support the general belief that foreign medical graduates, women, and members of ethnic minority groups are at higher risk for problems during residency. This observation emphasizes the need for increased openness, information, and understanding in these areas.

The 1970–1971 census of psychiatrists conducted by APA (11) indicated that 42 percent of all psychiatric residents were under the age of 30. Our group of problem residents were significantly younger (63 percent under 30, $p<.01$). Another significant finding relates to transfers between psychiatric residency programs. Based on data from 1969–1970, approximately 6.5 percent of the psychiatric residency population transferred from one program to another in a single year (11). Our sample of problem residents included 12 percent transfers, a significant difference ($p<.01$). This appears to be a definite high-risk factor and raises questions concerning the quality of interprogram communication.

Follow-up data for the 68 residents who did not com-

*$p < .02$.
**$p < .05$.

plete their residency year due to emotional illness indicated that 29 percent (N=20) transferred to another psychiatric residency program, 24 percent (N=16) were practicing medicine, 7 percent (N=5) transferred to a residency program in another specialty, 3 percent (N=2) were not practicing medicine, and 10 percent (N=7) were classified as "other." There was no follow-up information for 26 percent of the group (N=18). The large number of residents who transferred to another psychiatric residency program gives the impression of a group of mobile problem residents going from one program to another. Also of concern is the disturbing number of residents for whom no follow-up information is available.

Follow-up on the 220 residents who were able to stay in training despite marginal or failing performance and/or severe emotional problems indicates that three-fourths were urged to go into psychotherapy, but only half did. According to the judgment of the residency directors, 37 percent (N=81) of the residents who were kept in the program performed well, 48 percent (N=106) performed marginally, and 15 percent (N=33) performed badly. These figures indicate that the extra efforts of the residency programs were rewarded in 85 percent of the cases with at least marginal performance on the part of the residents with problems.

The survey also inquired about the applicant screening procedures the various programs used. The most common screening devices "always used" were letters of reference (used by 97 percent of the programs), faculty and staff interviews (87 percent of the programs), medical school records (68 percent), and interviews by residents (52 percent). Only 5 percent of the programs "always or sometimes" used psychological testing. Other methods reported included telephone contact with references, autobiographical sketches, etc. One program reported that it required applicants to interview a patient. Another reported that it obtained letters from past and present psychotherapists. One residency director stated that he talked to pharmaceutical representatives about the applicants.

When asked to rate the usefulness of the procedures they employ, only 30 percent of the programs rated letters of reference and medical records as very useful, although these procedures are virtually always used (see figure 1). The most useful procedures seem to be interviews by faculty members and by residents.

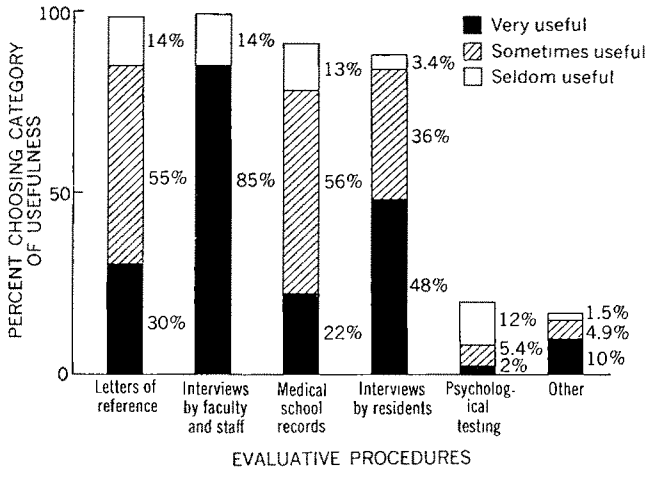
The most widely used evaluative and support procedures in psychiatric residency programs are reports by supervisors and faculty preceptors (see figure 2). Sixty percent of the programs always or sometimes used a resident sensitivity or therapy group. This important technique is the subject of another paper by one of us (12). It should be noted that programs recommended psychotherapy to residents in many instances, although this was not a built-in part of the program.

DISCUSSION

The task facing those who are responsible for psychiatric residency education is a large one. From among a highly successful group of applicants, the residency director needs to be able to identify a potentially disturbed resident before the stresses of psychiatric training precipitate the problem. Then the program needs to identify those individuals in training who are functioning below their potential and who are manifesting emotional problems. When these individuals are identified, the program needs to respond with the decisions, support, and treatment required. It is hoped that increased openness of discussion and further research concerning the problem of the emotionally disturbed and failing resident will make some of these tasks easier.

The problem is indeed great. In the single year of our

FIGURE 1
Psychiatric Residency Programs' Evaluations of Their Screening Procedures for Applicants, 1971–1972



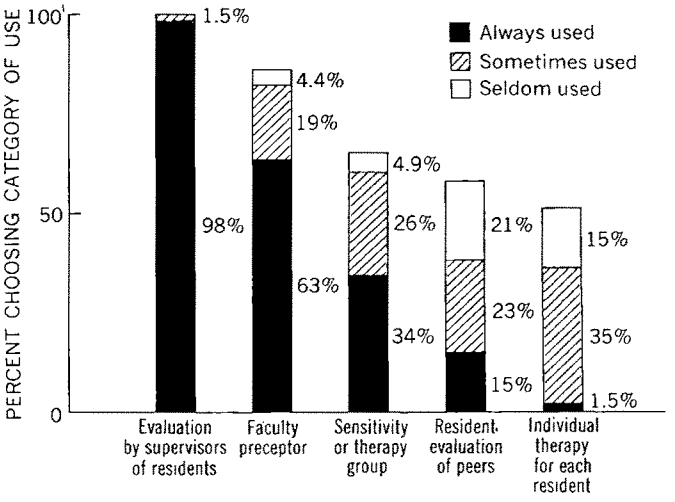


FIGURE 2
Evaluative and Supportive Procedures Used in Psychiatric Residency Programs, 1971–1972

study, 68 psychiatric residents had emotional difficulties of such magnitude that they were unable to complete their residency training. Even more tragic were the 4 suicides and their effects on the other residents and on the institutions involved. More than 8 percent of the residents we studied either did not complete their training because of emotional problems or remained in training despite marginal or failing performance and/or severe emotional illness. This means that a residency program of average size (N = 18 in our sample) will have an average of 1 or 2 residents each year with problems manifested in marginal performance, emotional illness, or (most likely) both. Thus, although Holt and Luborsky's observation (2) that "the great bulk of competent residents (and probably of good practitioners generally) are healthy, conventionally adjusted people" remains valid, the incidence of emotional difficulties among trainees remains a major problem for psychiatric education.

In order to identify the potentially disturbed or problem resident, we need more knowledge concerning the characteristics of residents who are at high risk for difficulties. In comparing our results with the available national data, we found that the incidence of problems among women, foreign medical graduates, and residents from ethnic minority groups was no higher than would be expected on the basis of distribution within the residency population. This finding perhaps will put to rest certain preconceptions, and it again emphasizes the need for more knowledge in this area. Significant factors that we found included a higher incidence of problems among younger residents and those who had transferred from other programs. We are currently gathering more precise data concerning the residency population as a whole in order to make further comparisons possible.

The magnitude and significance of the problem of the marginal resident underscores the need to devote more attention to evaluation procedures. Medical students and others who manifest significant problems should be identified, advised, and helped before they begin their residencies. Our results suggest that personal interviews by both faculty members and residents are the most helpful evaluative procedures and should be part of every resident's screening. Our results also indicate the need to explore other possible means of evaluation.

The high incidence of emotional problems among residents indicates that reliance on screening procedures alone is not enough. It is a common and disturbing experience for residency directors to accept a potentially successful resident who becomes unable to function under the stresses involved in residency training. Our survey indicates that almost all programs employ supervisor evaluations and a faculty preceptor. These practices are to be encouraged. Also of interest is the growing number of programs that employ a sensitivity or therapy group for residents. More research is required to establish the utility of these and other procedures.

Another conclusion that can be drawn from the results of our survey is that a large number of problem residents eventually perform well if they are given the required support and guidance. It is our feeling that this support should include the provision of psychotherapy in many cases. Residency programs may have to assume more responsibility in making this service available.

Our work in this study would be of little value if it did not stimulate thought and concern among those who are responsible for educating the psychiatric resident. In a period in which more and more competent psychiatrists are needed, every psychiatric resident who is unable to complete his training represents a significant loss to society and a waste of long and expensive training. Even more important is the personal loss and tragedy that surrounds so many of these cases. Yet the responsibility for identifying and preventing emotional decompensation goes beyond our own field. As experts in the evaluation and treatment of human behavior, we need to develop

new techniques in the evaluation of our own trainees that will benefit medical education as a whole. The fact that we have been unable to do this adequately so far is the final and perhaps most disturbing conclusion of this paper.

The Affective Experience of Residency Training in Community Psychiatry

BY PAUL G. COTTON, M.D., AND KYLE D. PRUETT, M.D.

The community setting arouses disturbing feelings (of anxiety, loneliness, anger, and disappointment) within the resident in a manner that is both unique and potentially constructive for his development as a clinician. The examination of these feelings in the supervisory setting and through peer supervision is crucial to the success of the resident's work in the community.

AS THE FIELD OF community psychiatry has matured, some experience in this area has become a recommended part of most approved psychiatric residency programs. In addition, an increasing number of reports on relevant training issues for new practitioners have appeared in the literature (1–3). However, in reviewing the literature on training programs, we have found that relatively little attention has been paid to certain complex and subtle subjective experiences that have a major impact upon the resident's growth and development. These are the affective, intrapersonal issues that are discussed in traditional psychotherapy supervision between supervisor and resident under the heading of "countertransference feelings." In practical terms this usually means the resident's personal reaction to a given psychotherapeutic situation.

We view the community psychiatric experience as a unique opportunity to examine a group of these feelings. In this paper we will outline the setting and supervision of our training experience, describe some of these feelings, give an example of the community experience, and conclude by considering some of the possible long-range effects that the community experience has had on our overall growth and development as clinical psychiatrists.

At the time this work was done, the authors were residents in psychiatry at Tufts-New England Medical Center Hospitals, Boston, Mass. Dr. Cotton is now Director of the Ambulatory Community Service, Cambridge—Somerville Mental Health and Retardation Center, Massachusetts Department of Mental Health, and Instructor in Psychiatry, Harvard Medical School. Dr. Pruett is Clinical Instructor in Psychiatry, Yale Child Study Center. Address reprint requests to Dr. Cotton, Department of Psychiatry, Cambridge Hospital, 1493 Cambridge St., Cambridge, Mass. 02139.

THE SETTING

The Tufts Mental Health Center, a part of the Massachusetts system of community mental health centers, consists of an affiliation of 17 agencies already existing in the South Boston-North Dorchester community. At the same time it is an integral part of the training activities of the Tufts Department of Psychiatry, a dynamically oriented training center of Tufts Medical School and the New England Medical Center Hospitals.

Residents in psychiatry spend their first year working primarily on the inpatient psychiatric unit of the Tufts-New England Medical Center Hospitals. During the second year they work with inpatients and outpatients of

Tufts Mental Health Center. The residents work in pairs. For six months one resident is the ward physician on one of three inpatient wards at the Austin Unit of Boston State Hospital, while his alternate works in the area of the community that admits patients to the ward. At midyear the residents switch positions.

It was our community work in the South Boston subdivision of our catchment area that generated our thoughts for this paper.

THE AFFECTIVE EXPERIENCE

The major affective experiences in our community training fall into four categories: anxiety, loneliness, anger, and disappointment. Obviously, these feelings are also central to the traditional psychotherapy situation in which the therapist is called upon to examine these feelings as they arise in his relationship with his patient. However, we wish to call attention to a similar need to acknowledge and examine them in the community experience, although the nontraditional roles and settings here can make this analysis more difficult. Just as the failure to acknowledge and work through these feelings can lead to an inappropriate disruption in a psychotherapeutic relationship, it can also lead to misunderstandings and unnecessary failures in community efforts.

The anxiety we are discussing was specifically related to the ambiguity that characterized the community training experience. This ambiguity was particularly striking when we contrasted it with our experience in a traditional inpatient setting where patients, clearly defined as such, came with complaints to us as residents in psychiatry. In community settings it is rarely as clear who is the patient, what is the role of the physician, and what constitutes treatment and improvement or cure. The ambiguity in the role of the physician extended from our vague perception of what skills we had to offer to the confused expectations of the people with whom we would work in the community.

Loneliness was experienced because the community work itself was often done in relative isolation from other medical colleagues and away from the main hospital facilities. We especially felt the loss of a shared sense of purpose with our colleagues. We missed our teachers in the office nearby. There was no such thing as a "coffeepot consultation."

Our anger was aroused by the suspicion and skepticism that we encountered in the people we met. They questioned our motives, reliability, and usefulness and distrusted even our "sacred" position as helping professionals. We were angry at this challenge to our professional self-images.

A final issue is the particular kind of disappointment we experienced, which stems from the nature of the community work itself. First, our fantasies of both the amount and quality of work we hoped to accomplish were clearly not met. Second, it is necessary to perform much more trial-and-error, preparatory work in a community setting than in the more defined, structured setting of the hospital. Initially, we felt that much of our time and effort was not productive. We felt fallow.

SUPERVISION

We now turn our attention to the role that two modes of supervision played in facilitating our awareness of the feelings previously described. The first was a traditional supervisory meeting held weekly between each of us and our clinical supervisor, a full-time member in our department who had had significant experience in community psychiatric work. These sessions dealt primarily with the more technical aspects of the consultation rather than the more subjective issues previously discussed. Although it is not the focus of this paper, we had a great deal to learn about the principles and mechanics of consultation. This learning took place primarily in the traditional supervisory sessions.

The second mode of supervision developed out of our working relationship, which was fostered by the structure of the residency program that paired the second-year residents. In order to establish some continuity between our experience on the ward and in the community, we scheduled a formal weekly meeting in which we discussed aspects of the community psychiatry experience. These meetings continued through the year regardless of which of us was working in the community. We noticed that these meetings evolved into discussions of our more personal reactions to the community work. We discovered that our personal reactions came up more fully and more frequently in these meetings than in our traditional supervisory meetings.

There were some obvious problems in our traditional supervisory meetings. Not only do residents often pay selective attention to those areas in which they do well, but also their ability to talk with a supervisor about interpersonal concerns varies widely with each resident-supervisor mix. Two residents who have known and worked with each other for more than a year have the potential for a trusting relationship that can allow access to their positive as well as negative personal reactions to their work. Most concretely, in this case we found it easier to tell each other that we were at different times anxious, lonely, angry, or disappointed. It was very valuable for our personal growth as well as for the success of our work to discover and examine the common situations that led to these feelings. In retrospect this seemed crucial to the success of the community consultation.

THE AFFECTIVE EXPERIENCE IN THE COMMUNITY

We selected the following case from our community experience in order to illustrate the affective experiences previously outlined.

After discussion with our staff supervisors, we decided to attempt to develop a consultation with the large urban high school located within our catchment area. At that time there was no formal consultation with the school;

however, its staff had expressed an interest in receiving some help from the mental health center. During the summer one of us (P.G.C.) visited the school to speak with the headmaster, the assistant headmaster, and the master in charge of the ninth-grade annex. At that time he introduced himself and expressed an interest in the possibilities of working together. He was received with some skepticism. The headmaster described how previous mental health workers had been more interested in their own training than in helping the high school. Another story was told about a group of mental health workers who had stopped coming to the high school when their own research project was finished. Despite these feelings the group offered to meet again at the beginning of the school year.

At that point in the first meeting it seemed that the school staff had accepted the offer to work together, and the resident became more active. Responding in part to the group's skepticism, he defined his time commitment—approximately one morning each week during the school year—and suggested that the group and he decide together what work could be done during that year. This gave a focus for the first meetings, allowed him to remain flexible, and gave him the opportunity to discover the main problems of the school as presented by the staff. As he left this meeting the resident felt good about the prospects for the fall.

The resident returned to the high school shortly after the beginning of the school year. Finding the front door locked, he rang the bell, and a teacher who had been sitting at a desk behind the door asked him who he was and what he wanted. After he introduced himself, she asked him for identification to prove that he was a physician working for the mental health center. She then telephoned the assistant headmaster's office and asked permission for him to enter. He was then admitted to the building.

He walked into the headmaster's office, which was crowded and obviously very busy. He announced his arrival to the secretary, who asked him to be seated. After he had waited for some time he was seen by the assistant headmaster, who said he was very busy since it was the beginning of the school year. The assistant headmaster suggested that the resident return the following week since he did not have anything specific to talk about with him. A similar series of events took place at the next two meetings.

After several mornings of this, the resident began to get angry. Different teachers were assigned to the front door of the school on a rotating basis. They were all suspicious, probably based on their unpleasant experiences with outsiders coming into and disrupting the school. This was the first time during his residency that the author had been mistaken for an interloper. He commented to his colleague that there might be more truth in this message than he was willing to admit.

At this point he was also disappointed. He had spent several mornings working in the community, and he still had difficulty getting in the front door. His anxiety was heightened by the continual lack of defined tasks. In contrast to his expectations, he had accomplished very little. He was also very lonely. He sensed that he was not wanted. The "enemy" was all around him. There were no friendly supervisors in the next office with whom to share these feelings. It seemed that the isolation of the setting heightened his feelings of anxiety, anger, disappointment, and loneliness.

It became clear in our discussions with each other that the recognition and understanding of these feelings were the prerequisite for our further work with the school. If the feelings had been projected onto the school, which was seen as rejecting, our efforts could have floundered. When we accepted the feelings as our own and began to explore them, we were able to develop means of dealing with the difficulties. For example, we planned to deal with the staff's suspicions by having the resident currently working with the school introduce himself to the teachers and guidance counselors, talking with the school nurse, and continuing to appear each week. We wanted to show them that their fears of him were unfounded. As he confronted the suspicion, the loneliness became less of a problem. By the fourth week the assistant headmaster was talking with him and the teachers and guidance counselors began to greet him when they saw him.

Eventually, over a period of about three months, he was able to apply his clinical skills. The assistant headmaster focused on behavior problems. The guidance counselors consulted him about difficult emotional problems. Occasionally, when a teacher was interested in making a particular point about mental health, he would ask the resident to sit in on the class. Then the resident discussed the presentation with him. From time to time he saw individual students. The other resident (K.D.P.) enjoyed a similar relationship with the staff.

There is a large body of literature on school consultation (4–8). Many of these observations were useful to us in the later aspects of our work in the school. However, we must reemphasize that the success of this work was dependent upon the attention we paid to the feelings generated in our initial contacts with the school.

CONCLUSIONS

Our experience in the community has given us the opportunity to acknowledge and analyze some of the differences between working in that setting and in the traditional mental health institutions and to examine some of our feelings when presented with these differences. We have found that the analysis of these feelings was crucial in terms of the effectiveness of our community work and was relevant to our personal growth as clinicians.

The process of doing community work and reflecting on it is a response in some sense to the professional drives toward independence and competence. The clinician can learn in another setting the importance of careful analysis of the nature of clinical material as it emerges both from himself and from the problems particular to community work.

Controversies in Psychiatric Education: A Survey of Residents' Attitudes

BY JOHN F. GREDEN, M.D., AND JORGE I. CASARIEGO, M.D.

The authors administered a questionnaire including statements regarding controversies in psychiatric education to 86 residents in six programs in the Washington, D.C./Baltimore, Md., area. The residents were asked for their opinions on educational policies, ideological issues in psychiatry, their identification with traditional areas of medicine, and future regulatory practices for psychiatry. The data gathered show some shifts in attitudes among first-, second-, and third-year residents. They also show a marked inclination toward dynamic-analytically oriented psychotherapy. The authors conclude that substantial changes will be required in the core curriculum of residency education if the prediction that tomorrow's psychiatrist will be a complete psychobiologist is to be fulfilled.

PSYCHIATRISTS ARE STRUGGLING with a multitude of controversies pertaining to such diverse issues in psychiatric education as the need for internships (1), the benefits of psychotherapy during residency (2), the desirability of the medical model or liaison with neurology (3–8), the value of social activism by psychiatric organizations (9), the relative merits of various therapeutic modalities and the ideologies on which they are based (10), the wisdom of periodic recertification (11, 12), and the future importance of psychoanalysis and neurochemistry (13).

The perceptions of psychiatric residents regarding these issues are important for a variety of reasons. First, residents are the consumers of our educational policies; as such, their perceptions may provide quality control information about the type of product our medical schools are turning out. Second, residents constitute a numerically substantial and outspoken segment of the profession; their support for contemplated changes in educational policies can be crucial. For this reason, and because residents appear more formative and flexible than established practitioners, rhetorical arguments often seem to be directed their way.

Third, residents are the future leaders of the profession. There is no guarantee that their viewpoints will remain stable in ensuing years, but residents' perceptions today may provide clues as to where psychiatry is headed tomorrow. For these reasons, we sought to determine how psychiatric residents in one part of the United States perceived some of the philosophical-methodological controversies being discussed at all levels of psychiatry.

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

At the time this study was conducted, Dr. Greden was Director of Psychiatric Research and Dr. Casariego was a third-year resident, Department of Psychiatry and Neurology, Walter Reed Army Medical Center, Washington, D.C. Dr. Greden is now Assistant Professor of Psychiatry, University of Michigan Medical Center, Ann Arbor, Mich. 48104, and Dr. Casariego is Chief, Psychiatry Clinic, 130th Station Hospital, Heidelberg, Germany.

METHOD

In May and June 1973, we personally administered questionnaires to 86 psychiatric residents in six residency programs in the Washington, D.C./Baltimore, Md., area. The 86 respondents represented 77 percent of all residents enrolled in the six programs. Eight of the residents

were at the Bethesda Naval Medical Center, Maryland (all of the residents in that program); 4 (67 percent of the program) at Freedman's Hospital/Howard University, Washington; 24 (63 percent) at Georgetown University Hospital, Washington; 7 (88 percent) at George Washington University Hospital, Washington; 17 (65 percent) at Sheppard and Enoch Pratt Hospital, Towson, Md.; and 26 (96 percent) at Walter Reed Army Medical Center, Washington. The educational policies of these programs have been described recently (14).

The residents whom we were not able to survey were, in most instances, on vacation, scattered to elective programs in other facilities, or busy when the questionnaire was administered. Twenty-six of the residents surveyed were in their first year, 31 in their second year, and 29 in their third year of training. Participation was voluntary, anonymous, and confidential; cooperation was generally excellent. No forms had to be discarded because of inadequate completion.

The questionnaire was a computer-tabulated, 21-page form with 120 items. It inquired about the resident's demographic and educational background, perceptions of the residency program in which he or she was enrolled, and whether he or she was receiving individual psychotherapy. Personal experience with various treatment modalities and ratings of these treatments occupied the major part of the form. (This information will be presented in another paper.) Thirteen questions dealt with controversies in psychiatric education. Responses to these items are the subject of this paper.

All statements that dealt with a controversy in psychiatric education were answered by means of a five-point Likert scale (15). The possible responses ranged from strong disagreement to strong agreement. Responses among residents in each of the three years of training were compared.

TABLE 1
Demographic Characteristics of 86 Residents

*$p<.05$ by chi-square analysis. The variables tested were: under 29 years old versus 29 years old and older; married versus single, separated, or divorced; having had an internship versus not having had one; and having received personal psychotherapy since residency versus not having received psychotherapy since residency.

**This category included behavioral, biological/organic, and community psychiatry.

RESULTS

Demographic data for the total group and for residents in each year are given in table 1. Several observations about demography were noteworthy. A much higher percentage of first-year residents did not report having had an internship. Religious activity was absent among most residents, and 28 percent reported that they had received psychotherapy before residency. Perhaps most important for considering residents' opinions in context, respondents in this population reported a conclusive predilection (62 percent) for a psychotherapeutic orientation.

Ratings of controversial issues are given in table 2. The initial controversy we inquired about was the internship dilemma. Forty-six percent of the 86 residents agreed that internship should be required before psychiatric residency; 39 percent disagreed. Not surprisingly, every supporter of the internship had taken one himself. Conversely, all those who had not taken internships (22 percent of the total population surveyed; see table 1) opposed the idea of requiring one. Since 42 percent of the first-year residents had personally avoided the internship year, a substantial proportion of the opposition was expressed by the first-year group ($p<.05$ by chi-square test).

Psychiatry's relationship with other branches of medicine was approached from several perspectives. First, respondents were asked about their own medical identity. The majority (58 percent) disagreed with the statement that they were a psychotherapist first and a physician only second. Despite this apparent support for a physician's identity, however, there was a coexisting disavowal of the traditional doctor's role of physically examining patients. Sixty-one percent of the residents disagreed with the statement that psychiatrists should conduct physical examinations on patients they plan to treat psychiatrically. Sixty-seven percent also felt psychiatrists should not perform rectal or vaginal examinations on their patients. These beliefs had apparently been present before residency or had developed early in the residency because first-year residents were identical to their second- and third-year colleagues in voicing little support for the role of physical diagnostician.

When asked to rate the statement that the medical model is outdated, one-third of all respondents agreed with this assessment. Interestingly, 57 percent of first-year residents disagreed with the idea that the medical

TABLE 2
Residents' Responses to Statements Regarding Psychiatric Controversies (N=86)

Statement	Residents' Responses in Percents: Strongly Agree or Agree	Neither Agree nor Disagree	Strongly Disagree or Disagree
Internship or its equivalent should be required before residency	46	15	39
My current identity is that of a psychotherapist first and a physician only second	26	16	58
Psychiatrists should personally conduct physical examinations on patients they plan to treat psychiatrically	13	26	61
Psychiatrists should not perform rectal or vaginal examinations on patients they plan to treat psychiatrically	67	17	16
The medical model of mental illness is definitely outdated	33	21	46
Psychiatrists in training should be required to rotate through a state mental hospital	23	24	53
All psychiatrists should conduct a research project before completing their residency	23	31	46
Compulsory periodic recertification of psychiatrists should be instituted (e.g., every five years)	49	27	24
Psychiatrists should not be required to take neurology examinations for board certification in psychiatry	47	4	49
Official organizations representing psychiatry (e.g., APA) should become more active in publicly recommending solutions for such social problems as racism, war, and poverty	48	12	40
Psychoanalysis is dying as an influential part of psychiatry	7	10	83
In the future, neurochemical discoveries will dramatically change psychiatry toward a medically oriented specialty	28	29	43
Psychiatrists are extremely susceptible to fads in considering new treatment approaches.	26	25	49

model is outdated compared with only 44 and 32 percent, respectively, of the second- and third-year groups ($p<.05$ by chi-square test).

Since criticism has been expressed about maldistribution of psychiatrists, residents were asked whether they felt state hospital rotations should be required during residency. There was clearly little support for this policy. Responses differed significantly, however, among first-, second-, and third-year residents. Only 35 percent of the individuals in their first year of training disapproved of state hospital rotations compared with 57 percent of second-year respondents and a startling 72 percent of third-year residents. There was also little approval expressed for the requirement of research activity during psychiatric residency.

Two items on the form dealt with certification policies. Almost half of all respondents agreed with compulsory periodic recertification; 24 percent disagreed. Most of those who disagreed were third-year residents. On the second certification issue, the 86 residents split almost evenly when asked whether psychiatrists should continue to be required to pass a neurology exam for board certification in psychiatry. Forty-seven percent felt this requirement should be dropped and 49 percent advocated continuation. Differences were again apparent according to year of residency. Only 22 percent of the first-year residents felt that neurology should not be required compared with 57 percent of second-year and 62 percent of third-year respondents ($p<.01$ by chi-square test).

A variety of miscellaneous statements were also rated by the 86 residents. Social activism on an organizational basis, e.g., through official policy statements of APA, was approved by 48 percent but disapproved by 40 percent of the residents. No differences were found among first-, second-, and third-year respondents for this item. The intensity of feeling on this issue was reflected by the fact that 15 percent strongly agreed and 16 percent strongly disagreed.

The one expression of relative unanimity among this group of residents occurred in response to the statement that psychoanalysis is dying as an influential part of psychiatry. Eighty-three percent of all respondents supported analysis in their ratings of this statement. A meager 7 percent appeared ready to sound the death knell of analytic influence. In rather stark contrast to this support for analytic approaches, only 28 percent of all the residents agreed with the statement that neurochemical discoveries will alter the future practice of psychiatry.

When asked whether they felt psychiatrists are susceptible to fads when considering new treatment approaches, 49 percent of the residents disagreed. However, this was still less than a majority. Twenty-six percent of the respondents agreed with this blatantly critical statement of treatment trends in psychiatry.

Residents were also asked to rate the importance of personal psychotherapy in becoming a good psychiatrist. Their responses to this item are shown in table 3. More than half of all the residents considered it extremely important and 29 percent rated it moderately important. Nineteen percent considered it minimally or not important. Predictably, every resident who rated therapy unimportant was not receiving therapy. Less predictably, but still consistent, all residents receiving therapy rated it either moderately or extremely important.

DISCUSSION

The topics evaluated in our questionnaire did not focus upon a single theme. Rather, they pertained to educational policies for residents, ideological issues plaguing psychiatry, identification with traditional areas of medicine, and future regulatory practices for the profession.

Several trends were identified. When the total sample

was considered, the majority of residents disagreed with any policy that would require research projects or state hospital rotations during residency. They disagreed with the concept of psychiatrists' conducting physical examinations, especially rectals or vaginals, on patients they treat psychiatrically. They did not foresee that neurochemical discoveries would change psychiatry and denied that psychoanalysis was dying as an influential part of the profession. Many residents supported reinstitution of the internship, but only if they had taken one themselves. Almost one-half supported compulsory periodic recertification, but one-half also wanted to eliminate neurology from the certification examinations for psychiatry. Social activism by official organizations of psychiatry was supported by 48 percent of the residents but disapproved by 40 percent. Psychotherapy was generally rated an important part of residency education.

This study was not a longitudinal assessment of the same individuals throughout their residencies, but several apparent shifts can be cautiously observed when first-, second-, and third-year residents are compared. A higher percentage of those nearing the end of their training were against state hospital rotations, against compulsory resident research, against inclusion of neurology in psychiatric certification examinations, and against compulsory periodic recertification. Third-year residents also expressed less support for the medical model and for the future importance of neurochemical discoveries.

Conceivably, residents in the later stages of training may have responded differently because of increased experience or knowledge. It would be difficult to justify their greater skepticism toward neurochemical discoveries on a scientific basis, however. Most of the items we assessed were subjective; there is little significant documentation to support one view or another. We therefore conclude that the opinions expressed by residents in each year of training were formulated largely through a process of unscientific extrapolation dependent upon the resident's psychiatric set or ideological identity.

Longitudinal evaluation would be required for definite confirmation, but we would speculate that as the resident's ideological identity changes during residency, his opinions regarding controversial issues are modified to conform. In this context, it is noteworthy that more than 57 percent of residents in all three years described themselves as dynamic-analytically oriented and that, although 33 percent of all residents described themselves as eclectic, these individuals differed from analytically oriented respondents only in their greater acceptance of behavioral therapy techniques. Eleven percent of the residents in their first year of training categorized themselves as oriented toward behavioral, biological/organic, or community psychiatry, but among second-year residents only 3 percent adhered to this identity; none of the third-year respondents described themselves with these labels.

Armor and Klerman (16) classified psychiatrists into psychotherapeutic and somatic. According to this distinction, a startling 95 percent of residents in our survey would be categorized as more or less psychotherapeutic. If the predominance of this psychotherapeutic ideology is taken into consideration, the responses reported on controversial issues are generally more understandable.

TABLE 3

Perceptions of the Importance of Personal Psychotherapy in Becoming a Good Psychiatrist Among 86 Residents

Rating of Importance of Psychotherapy	Percent of Residents Giving Rating			
	All Residents (N=86)	By Year of Residency		
		First (N=26)	Second (N=31)	Third (N=29)
Extremely important	52	54	48	54
Moderately important	29	27	29	32
Minimally important	8	8	13	4
Not important	11	12	10	11

Caution must be taken, of course, in generalizing these findings to residents in other parts of the country. The Washington/Baltimore area has a long-standing tradition of emphasizing psychotherapy. Ideological approaches elsewhere may be substantially different. If so, perceptions of controversial issues might also be different.

West (1) described the psychiatrist of tomorrow as "more of a neurobiologist, more of an endocrinologist, and more of a behavioral scientist than the psychiatrist of today." Similarly, Myers (17) referred to the psychiatrist of tomorrow as the complete psychobiologist. These formulations for the future are obviously not being adhered to by the majority of the residents we surveyed.

Paradoxically, five of the six programs assessed in this study generally described themselves as eclectic in the *Descriptive Directory of Psychiatric Training Programs* (14). Yet when residents' attitudes, experiences, ideological orientations, and ratings of treatment modalities were considered, it appeared illusory to consider the products of these programs as being truly eclectic. Most were clearly psychotherapeutic at the time of the survey.

We suggest that psychiatric residents have a propensity to drift toward endeavors that they find enjoyable or compatible with their ideological set; global manpower considerations and scientific data seem to exert little influence in career directions. If the production of complete psychobiologists is truly the professed goal of residency education programs—a viewpoint that certainly lacks universal agreement—the unpleasant reality appears to be that this goal can be reached only after program directors establish rigid core curriculum standards that all residents must adhere to. Most residents—at least in the Washington/Baltimore area—do not appear inclined to choose the exacting course described by West and Myers.

It might be worthwhile for program directors to assess and publish the orientations and types of practice their graduating residents have selected (18). Such data might furnish incoming applicants with a more accurate appraisal of residency programs than published statements of intent do. Such studies might also generate precise data to embellish planning sessions about future trends in psychiatric education.

Attitudes of Psychiatric Residents Toward the Necessity of Internship

BY TOKSOZ B. KARASU, M.D., STEFAN P. STEIN, M.D., AND EDWARD S. CHARLES, M.A.

The authors note that the elimination of the internship requirement for board certification has engendered much discussion and has called attention to the need for further study of training in psychiatry. To help clarify the issue, they investigated demographic and career choice factors, individual internship decisions, and perceptions and feelings about these decisions in 57 psychiatric residents. The results indicate that the career plans of students have a strong influence on their training choices—those who are oriented toward inpatient psychiatry and psychosomatic medicine view the internship as more relevant than those who plan to concentrate in other areas. The authors suggest further research on the relation between career choice and training preferences.

PSYCHIATRIC education has recently become the subject of study and controversy. As they have moved into the mainstream of university medical settings in recent years, psychiatric training programs have reflected changing trends in the field of psychiatry.

The 1940s and 1950s were marked by a great emphasis on dynamic psychiatry. Psychoanalytic psychology became integrated into the body of psychiatric knowledge and psychoanalysts brought their expertise to many training programs. In the 1960s, social and community psychiatry added another dimension, paralleling changes in American medicine at large. In addition to teaching the "technology" of psychiatric practice, many other issues were raised, such as health care delivery, coordination with other caretakers, and consumer participation. Most recently, advances in neurochemistry and neuropharmacology have not only increased scientific curiosity among psychiatrists but have also created a renewed "medical" outlook for the future of the profession.

One may speculate that a "return to medicine," if one may use that designation, would tend to further the influence of general medicine on psychiatry. In eliminating the requirement of internship for certification, the American Board of Psychiatry and Neurology was following the pattern of other medical specialties. The decision to permit direct entry from medical school into residency

The authors are with Bronx Municipal Hospital Center, Pelham Parkway South and Eastchester Rd., Bronx, N.Y. 10461, where Dr. Karasu is Associate Director, Department of Psychiatry, Dr. Stein is Director, Psychiatric Outpatient Services, and Mr. Charles is Research Associate. Dr. Karasu is Assistant Professor and Dr. Stein is Assistant Clinical Professor, Department of Psychiatry, Albert Einstein College of Medicine of Yeshiva University, Bronx, N.Y.

training programs has engendered a great deal of discussion and opinion. Some educators have warned that the quality of the education of the future psychiatrist may be adversely affected, while others feel that psychiatrists may be well-trained without a formally designated internship (1, 2). However, few studies have addressed these issues in a systematic way.

In an earlier study (3), we compared the work of internship-trained first-year residents with that of a matched noninternship group on a psychiatric inpatient service. A chart review comparison revealed differences in patient care practices in the areas of length of stay, writing of progress notes, and use of the laboratory and of medical consultants. Staff ratings of the two groups of residents were found to differ significantly on four of five categories. The data from this study suggested that residents without internships were at somewhat of a disadvantage in their work in this inpatient setting. Internship appeared to improve the resident's ability to handle certain medical-psychiatric aspects of inpatient care.

The question may be raised whether the differences we noted in that study may diminish in later years of residency training and whether there will ultimately be any measurable differences between the two groups. In addition, that study was conducted on an inpatient service, and the results may not be generalizable to other types of psychiatric practice, such as community psychiatry or outpatient psychotherapy. The relevance of the internship may depend in part on later career interests of the particular resident.

This paper reports a systematic attempt to examine the attitudes of a group of residents toward the elimination of the internship. While we are emphasizing the future career plans of the residents, their backgrounds and personal characteristics were also studied.

METHOD

The study was conducted on the psychiatric service of the Bronx Municipal Hospital Center, Bronx, N.Y. The psychiatric residency program of the Albert Einstein College of Medicine of Yeshiva University has been staffing this service since its inception in 1955. There are approximately 18 residents in each year of training. The first year is spent on the inpatient service of the Abraham Jacobi Psychiatric Unit, Bronx Municipal Hospital Center.

The second and third years are spent in the outpatient department, which consists of adult and child-adolescent clinics. A variety of treatment approaches are taught, ranging from group-milieu approaches to long-term individual insight therapy to the use of psychoactive drugs and other somatic therapies. Rotating consultation to other medical services is part of the first- and second-year assignments.

A full program of seminars related to the study and treatment of individuals, families, and groups complements the resident's supervision and clinical work. Current theories of causation of the major psychiatric illnesses are presented in an atmosphere of eclectic learning. The curriculum is similar to that of other major East Coast psychiatric programs in its approach to training and patient care. The residency program began to accept residents without an internship in 1970.

All residents in the program (N=62) were asked to complete a comprehensive survey regarding attitudes toward the internship in psychiatric education. The survey also investigated social and demographic characteristics and career plans of the residents. Open-ended questions inquired into reasons for residents' individual choices of internship versus no internship and their perceptions of the effects of this decision (if the option had been available to them).

RESULTS

Of the 62 residents in the program, 57 (94 percent) completed the survey. Fifty of the respondents (88 percent) were internship-trained residents and 7 (12 percent) were noninternship-trained residents. Table 1 presents demographic data and career plans for the 57 respondents. Eighty-one percent of the residents were men and 19 percent were women. Their ages ranged from 26 to 38, with no significant distribution differences between the internship and noninternship groups. Two-thirds of the residents were married. The career plans of almost all of the respondents included private practice and teaching; 6 residents (11 percent) planned psychosomatic medicine liaison work.

On the attitude survey (see table 2), 69 percent of the respondents agreed with the statement that an internship should be a prerequisite for psychiatric residency. Of the 25 percent who strongly agreed, all were in the internship

TABLE 1
Characteristics of Psychiatric Resident Respondents (N=57)

Characteristic	Number	Percent
Sex		
Male	46	81
Female	11	19
Age		
26–27	12	21
28–29	26	46
30–31	11	19

Psychosomatic medicine	6	11

TABLE 2
Residents' Responses to a Survey of Attitudes Toward Internship, in Percents (N=57)

Item	Disagreement	Slight Agreement	Moderate Agreement	Strong Agreement
1. An internship should be a prerequisite for psychiatric residents.	31	18	26	25
2. An internship is totally unnecessary as preparation for psychiatric residency.	63	14	19	4
3. An internship is an asset, but not essential, in preparation for psychiatric residency.	18	10	25	47
4. Psychiatrists should not attend medical school, but should be prepared in a special interdisciplinary graduate school program, with emphasis on psychobiological and social sciences.	37	25	22	16
5. If you were presently a third-year medical student and planning a psychiatric residency, would you take an internship?	No—37		Yes—63	

group, while all of the noninternship group were among the 31 percent who disagreed. Thirty-seven percent agreed with the statement that an internship is totally unnecessary, while 82 percent agreed with the statement that an internship is an asset but is not essential in preparation for psychiatric residency.

The statement that psychiatrists should not have to attend medical school was answered "strongly agree" by 16 percent of the residents, all of whom had internship backgrounds. Among the 36 residents who stated that they would take an internship if they were third-year medical students now, there were 2 who had elected not to take an internship.

Responses to the open-ended questions of the attitude survey generally identified greater ease in medical management and increased self-confidence in the role of physician as benefits accruing to the beginning psychiatric resident from internship. Sample comments excerpted from responses of the internship group to the open-ended section of the questionnaire include the following:

"More comfortable with responsibility for patient care and more confident in my role as a doctor."

"My beginning residency was less of a stress; internship helps speed clinical maturity."

"Without an internship, you're not a real doctor."

From the noninternship group came these comments:

"I felt slightly less prepared and less comfortable with patient responsibility."

"Did not feel confident in my ability to make medical decisions at the beginning."

"Having had it would have made moonlighting possibilities greater."

Most of the comments from both groups were consistent with these examples.

DISCUSSION

The effect of elimination of the internship may be quite different for psychiatry than for other medical specialties. The type of experience gained during an internship is often contained within the first year of residency in other medical specialties. Residency training in psychiatry may not similarly compensate for the absence of the internship year. For residents in psychiatry, bypassing the internship phase may have a different implication regarding their interest in and attitude toward medicine, as well as their future career direction. Thus direct entry into a psychiatric residency may have not only a "telescoping" effect but also a divergent effect that encourages early departure from a medical orientation.

There is a broad spectrum of practice opportunity within psychiatry, ranging from medical and biological research and hospital practice to social and community psychiatry. Career plans within the field of psychiatry may define the usefulness of the internship experience. This study focused on the relationship of specific career plans to the decision whether or not to take an internship.

All noninternship residents disagreed that an internship should be a prerequisite for psychiatric residency, although 2 of them stated that they would take the internship if they were currently third-year medical students. This option was, of course, available to them, and they elected not to do so. Thus, the fact that the internship is not mandatory may lead to the prospective resident's belief that it is not useful or necessary. Some noninternship residents indicated that they would have taken an internship in spite of their views that internship should not be a prerequisite. Such conflicting statements may reflect a negative attitude toward requirements in educational institutions that may be prevalent. On the other hand, 21 of the respondents (advanced residents who had not had the option of direct entry into residency) stated that in retrospect they would not have taken an internship if they had had a choice, even though they all viewed the internship as a valuable experience.

Valuable experiences may not necessarily be viewed as desirable. In addition, as a resident advances and becomes more distant from the care of the acutely ill psychiatric inpatient, his view of the relevance of an internship may be modified by that distance and by the development of a new professional identity, that of "psychiatrist." All of the 6 residents (11 percent of the sample) who planned a career in psychosomatic medicine were among those who had taken internships and who reported on the survey that they would make the same choice again.

The career choice of all of the noninternship residents

and 37 percent of the internship residents excluded psychosomatic medicine and research. This segment of the internship residents was among those who agreed with the statement that they would not have taken an internship if they had had the option. Their future career plans were directed toward psychotherapy, teaching, and community mental health work. Thus, the career direction of the resident appears to influence his view of the usefulness of the internship, as well as his decision whether or not to take it.

The data suggest that career plans play an important role in determining the type of training an individual arranges. An internship is viewed as particularly relevant by those who plan a career in psychosomatic/liaison medicine or inpatient psychiatry. The relevance of an internship for those whose career plans include outpatient psychotherapy or community psychiatry is an open question. Further study exploring the relationship of career choice to training in psychiatry is needed.

Career Decisions in the Early Postresidency Years

BY JAMES L. CAVANAUGH, JR., M.D.

The author notes that the end of the postresidency military obligation necessitates earlier career decision making for the senior psychiatric resident. This problem is seen to be exacerbated by the eclectic nature of most psychiatric training. Issues for residents include the problem of role models and the "senior resident syndrome," the decision of whether to maintain their university affiliation, the role of private practice, questions of clinical maturity, etc. The author believes that programs must be developed to systematically and objectively present to residents the data that now exist regarding multiple career options.

WITH THE disappearance of the postresidency military obligation, the senior psychiatric resident is forced to make decisions on career directions at an earlier time than ever before. Whereas some form of government service (e.g., military, Public Health Service, or Veterans Administration) has traditionally given the majority of newly trained psychiatrists two additional years of structured clinical, administrative, or research opportunities, the termination of the doctor draft, the CORD program, and the Berry plan will now present all senior psychiatric residents with a similar dilemma—what to do professionally in the early postresidency years. For the university-based, eclectically trained resident—a description that fits a majority (54 percent) of all residents (1)—decisions about career directions are particularly difficult. Assistance in exploring these questions has not classically been a significant function of the medical-school-based residency experience, and the majority of newly trained, eclectic psychiatrists have heretofore used government service as a period for debating, reflecting, and decision making about future goals.

Numerous studies (2–6) over the years have explored the diverse issues involved in the process of residency training. Relatively little study has been devoted, however, to the issues raised by the early postresidency years and the problem of multiple choices for career direction. It is imperative that departmental chairmen and directors of residency training programs begin to explore more fully ways to help all psychiatric residents deal with these crucial early postresidency decisions about career directions. This paper will explore various issues raised in career decision making for the eclectic resident.

Read at the 127th annual meeting of the American Psychiatric Association, Detroit, Mich., May 6–10, 1974.

Dr. Cavanaugh is Assistant Professor of Psychiatry, Rush Medical School, and Clinical Director, Department of Psychiatry, Rush-Presbyterian-St. Luke's Medical Center, Chicago, Ill. Address reprint requests to Dr. Cavanaugh at 1310 Ritchie Ct.-22D, Chicago, Ill. 60610.

ROLE MODELS AND THE "SENIOR RESIDENT SYNDROME"

Role modeling after mature psychiatric teachers clearly has a very powerful influence on resident behavior and professional identification. Brody described the process as

> the unconscious acquisition (following some conscious imitation) of some of their ways of thinking, feeling, and acting. Such identification and its eventual dissolution, leaving key residuals integrated with precipitates of other important relationships, is an essential aspect of the maturation process without which learning is merely the cross-sectional reception of information. (7, p. 155)

For today's eclectic resident, the predominant role model remains the "triple-threat" psychiatrist (clinician, teacher, and research professor) originally described by Sharaf and Levinson (8). Exposure to these career sets, exemplified by the most prestigious academic psychiatrist, at crucial times during their development creates for the majority of psychiatrists in training an awesome professional goal. Many (perhaps most) senior residents are uncomfortable with this complex role model or feel inadequate to live up to it. Understandably, these individuals experience anxiety, confusion, and even depression as the time for career decision making approaches. To make a mature decision, they must reexperience old conflicts about role confusion initially struggled with as part of the beginning psychiatry training syndrome (9). At best, the triple-threat role model has only been partially assimilated and mastered, or partially rejected and other models incorporated. Professional identity versus professional identity diffusion, analogous in part to the crisis in adolescent development described by Erikson (10), characterizes what may well become a new syndrome—the "senior resident syndrome"—created by the eclectic dilemma and accentuated by the termination of two years of required postresidency military experience. Finally, the eclectic psychiatrist, as recently reviewed by Abroms (11), has no theoretical framework to replace the integrative function of psychoanalytic theory. Career preceptorships and special seminars must be developed in eclectic residency programs to help all residents explore more fully the complex personal and professional issues raised by the senior resident syndrome and the role model of the academic psychiatrist.

CLINICAL MATURITY AND THE RETREAT FROM THE PATIENT

University-based residency programs have emerged as the most prestigious centers for psychiatric training. This academic and research orientation in residency training has dramatically expanded the data base of the eclectic psychiatrist and has resulted in greater respectability for psychiatry within the university medical center. Kubie, however, recently called attention to an alarming pattern developing in academic centers of medicine.

> It is a disease without a name whose presenting symptom is a retreat from patients. . . . The flight from patients is even better rationalized, culturally supported, and to a dismaying degree practiced, defended, and approved by many eminent psychiatrists. (12, p. 101)

For the bright young man in a hurry academically, the triple-threat role model is perhaps an appropriate one, but its contribution to the continuation of the development of clinical maturity is more dubious. Clinical maturity still remains the cornerstone of psychiatric judgment, and Kubie further stated that if the eclectic is to be well trained, "He must first become a psychiatrist. . . . In the process of 'becoming,' an indispensable ingredient will be long and intensive involvement with individual patients" (12, p. 99). For the gifted resident, comfortable with and able to follow the academic role model, intensive clinical involvement with patients is the activity least likely to be rewarded by peers because it is most difficult to evaluate objectively and therefore may be underemphasized in early career decisions. For the average resident who is unable or unwilling to follow the triple-threat model, selection of a subspecialty career tract (administrative psychiatry, research psychiatry, full-time academic psychiatry, forensic psychiatry, or social and community psychiatry) in an attempt to excel in one area could result in "selective inattention" to meaningful personal involvement with patients. All residents approaching career decisions must carefully explore the implications of such subspecialty choices for their further clinical maturation.

UNIVERSITY AFFILIATION

With the majority of residents now being trained in the university system, one early career decision must deal with continuation or discontinuation of the university affiliation. Although few authors have discussed the issues involved in these decisions, Romano (13) and Engel (14), in their writings on the concern that psychiatry is withdrawing from medicine, have clearly stated that at least some work within the medical school setting is crucially important to the psychiatrist's continued evolution as a competent professional. However, discussions of the relative advantages and disadvantages of salaried full-time, geographic full-time, part-time, or donated-time positions are rare. The question of staying at one's training institution versus moving on to other centers and other opportunities is rarely debated. In many major university centers, graduated residents stay on in minor staff positions, causing such saturation of psychiatric talent in certain areas of the country that creativity and personal development are often smothered. Failure to be "accepted" on the staff is often seen as complete rejection of one's worth as a psychiatrist. Opportunities in other geographical areas or in newer, less known, less developed departments of psychiatry are not explored, perhaps again partially due to the prestige and relative safety of working in the parent university, which is reinforced by the presence of the local academic role models.

Many myths need to be carefully explored in considering types of university affiliations. For example, the relative merits of salaried full-time versus geographical full-time positions have been recently examined by Maloney in one of the very few well-designed investigations of this question.

> For nearly half a century, GFT (geographic full-time) faculty members have been considered to be economically motivated, to do little research, to have minimal extra-mural grant support, to be distracted from their teaching obligations by clinical practice, to spend little time with students, to neglect administrative matters, and to lack scholarly distinction. In contrast, SFT (salaried full-time) faculty are viewed as having intellectual rather than economic motivation, to engage actively in research, to have abundant grant support, to spend much time teaching, to be available to students, to carry a heavy administrative burden, and to achieve national and international recognition for scholarly activities. . . . Interestingly, all but one of these shibboleths are false. (15, pp. 5–8)

Maloney noted that all but one of these stereotypes were false (salaried full-time faculty did spend more time in research-related activities). Other myths for consideration might include the following: 1) the prestige of faculty appointment outweighs all other considerations (financial sacrifice, etc.), 2) the acquisition of tenure is a most important consideration in weighing academic affiliation, 3) patients prefer to be cared for by the university physician, 4) competence as a specialist is related to the degree of involvement in the medical center setting, and 5) medical students and house staff learn "most" from academically oriented teachers. These and other diverse issues regarding academic affiliation must be discussed with eclectic residents who are trained within the university setting.

THE ROLE OF PRIVATE PRACTICE

Private practice remains a relevant professional activity worthy of consideration by the newly trained psychiatrist (16). Kubie has observed, "Private practice has many defects, but in spite of them it has been our best teacher for years" (12, p. 99). The role that private practice can play in the continued evolution of clinical maturity should be abundantly clear to even the casual observer interested in psychiatric training. Personal involvement with patients, whether the modality is individual, marital, family, group, or community therapy, is a basic role model requiring careful consideration by every psychiatrist. Few eclectic training programs, however, offer significant opportunities for senior residents to explore with private practitioners of psychiatry the many complex issues involved. In fact, the classic salaried full-time system interdicts private practice or allows only a group or a professional association practice in which definite financial advantages exist for the department or sponsoring organization.

The negative set that exists in many academic psychiatric communities toward private practice is such that not only are discussions of the problems and advantages of private practice completely avoided but clinical teachers who are actively engaged in private practice are frequently devalued and become negative role models for training residents. In a recent survey of practicing psychiatrists in Florida, Warson and Denman (17) found that 28 percent of the psychiatrists surveyed felt that their formal residency programs trained them less than adequately for the problems they encountered in psychiatric practice, and 83 percent felt a lack of preparation for the necessary practical aspects of private practice. Allen, who was successful in organizing private practice seminars for senior residents at the University of Cincinnati, found that a very significant factor was "the residents' need before they severed their ties to their training institution for an opportunity to expose and discuss problems that they might expect to encounter in their role as (practicing) psychiatrists" (18, p. 418). Few eclectic programs offer such discussion groups as a part of formal residency training.

PERSONAL PSYCHOTHERAPY OR TRAINING ANALYSIS

The role confusion typically experienced by first-year residents is reawakened as they struggle with decisions on career directions in the early postresidency years. Dynamic eclecticism, with its systematic rather than theoretical cohesiveness, presents the young psychiatrist with multiple career directions but no unitary ethical, theoretical, or philosophical position. Academic role models are presented for emulation that may not be appropriate to the residents' career goals or professional potential. It is perhaps possible to speculate that senior residents and young psychiatrists will now seek personal psychotherapeutic experiences not primarily for purposes of training but at least in part to assist them with career decisions and with understanding their underlying conscious and unconscious motivations. Further, the eclectic resident has difficulty discussing these decisions with faculty who are often too busy to listen or too "powerful" for residents to approach comfortably. Career preceptors are rare in training programs, and career seminars are infrequent. The senior resident is essentially alone and anxious as he approaches this important crossroad in his young career. Some authors have noted the waning of psychiatric interest in formal psychoanalytic training, but many young psychiatrists are still engaging in their own personal psychotherapeutic experiences (19). Pressure for earlier career decisions, in part related to the present discontinuation of obligatory government service, could strengthen this trend, which is considered a healthy one by many. Thus an important experience could be added to the residency years in a manner that is perhaps more responsive to the individual needs of residents than the earlier imperatives for formal analytic training, which often succeeded in only further compounding the dilemma of the early postresidency years.

CONCLUSIONS

The need of the senior eclectic resident for thoughtful career counseling has increased as the discontinuation of obligatory postresidency government service adds to the dilemma of career decision making. Whatever the resident's ultimate choice of early career directions, departmental chairmen and residency directors must attempt to develop programs to objectively present the vast amount of data that now exists regarding multiple career options. It is important to note that academic role models are not necessarily the only appropriate models for emulation by all residents. Career preceptors should be developed within the university-based training program to help senior residents work through what has been described as the senior resident syndrome. Formal or informal seminars fully sanctioned by the department should become foci for discussion of such career decision issues as the importance of clinical work in the further development of psychiatric judgment, facts about university affiliation, the role of private practice, and the desirability of personal psychotherapy.

EDITORIAL

The Ideal Physician

IN A RECENT COMMENTARY in the *Journal of the American Medical Association*, Dimond (1) highlighted the desirability as well as the difficulty in selecting scientifically qualified medical students possessing the personal quality of compassion—a generally accepted characteristic of the ideal physician. In another *JAMA* article, Pellegrino (2) proposed that historically and practically, achieving a consistent triad of excellence in skill, knowledge, and humanistic attitudes (the ideal physician?) is perhaps unlikely except for a "very few persons."

The ideal physician has been described as a compassionate medical scientist (1), as a humanist physician (2), and as one who practices "the art and the science" of medicine (3). What is meant by "compassionate," "humanist," or "art" when one is defining the qualities of an ideal physician? If one cannot define these specific qualities, how then can one proceed to select such a person or develop enhancing educational programs for him?

There seems to be little debate about what a scientific physician is: he or she must base his/her professional skills and practice on the foundations of scientific discovery, on information and techniques acquired by employing the scientific method (and tolerated amounts of logical, deductive reasoning). But when you ask six people to define a compassionate or humanist physician, the usual responses consist of a variety of six commonly agreed upon examples; rarely do they provide a useful or clear definition.

Any effort to deflocculate these muddy waters should identify some basic personality characteristics of the ideal physician that can be teased out and perhaps measured, or at least evaluated. One possibility is that compassionate, humanist, or "ideal" physicians are those who are aware of and concerned with the secondary, affective, and peripheral consequences to their patients of their primary cognitive decisions and scientific activities. Similarly, such physicians are aware of and concerned with the potential cognitive impact on the patient of their own affective responses. Underlying this is the indispensable assumption that the physician possesses an adequate base of scientific knowledge and skill. But if he is to function as an ideal physician, these skills must be practiced within a humanistic framework that implies an empathic attitude toward patient concerns, an attitude that permeates the application of those indispensable scientific accouterments. Aware of their own emotions engendered by the patient-physician interaction, such professionals utilize their energies (anger, love, etc.) for their patient's welfare, not their own, or neutralize these responses effectively in the patient's interest. They foresee and sensitively anticipate the patient's anxiety about his ailment and have the ability to share this awareness either directly, by word, or indirectly, by deed, in a way that tends to replace patient fears with legitimate confidence in the physician.

A recent student-teacher clinic provided a simple example for evaluating medical student humanism, or its potential. A child neurologist and I (a child psychiatrist)

In this section the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

were teaching four medical students the key diagnostic features of a mongoloid child. As each of the students examined the child and her epicanthal folds, noted the simian lines across her palms, demonstrated the laxness of her joint ligaments and her muscular hypotonia, one of the students spoke up spontaneously: "Shouldn't we have washed our hands before examining the child?" He was concerned about the sudden and massive application of bacteria, etc., by 12 hands holding, flexing, and rubbing over the nearly naked baby. His sensitive concern was for a possible consequence secondary to the primary cognitive examination activity itself. It was a clue, if one accepts my hypothesis, that this student had the potential for becoming a compassionate medical scientist. His comfort with speaking up about the faculty's failure to suggest this precaution also indicated that he believed he was in an environment that could tolerate compassion and even reward it (he was praised for his alert and appropriate sensitivity).

This example is from the same cloth as that of the physician who warms the stethoscope, takes the time to explain in advance unfamiliar sensations to expect during an examination, or tells a patient that crying with relief is a beautiful thing—and then comfortably allows it to happen.

Both in actual teaching-learning situations and in simulated educational clinics such qualities can be observed, encouraged, perhaps taught, and certainly rewarded. Identification of the personality traits I have described could represent one predictive step across the quicksands of identifying compassionate science students for medical school admission.

An educated awareness of and concern for the affective component of the patient's being tempers and guides the empathic yet calculated, the objective, and the cognitive decisions of the ideal physician. Physicians are advisors, not dictators, in the sense that they give advice and not orders to the patient. They give this advice as freely as they give the patient the privilege of accepting or rejecting it without retribution. They possess the ability to share in the patient's helpless or seemingly hopeless plight while remaining effective in their proper attitudinal attire of knowledgeable hope.

The one common personality thread found in the fiber of an ideal physician may be this educated sensitivity, this sympathic resonance with the patient, which does not affect the physician's objective decision making as much as it affects his style and manner of rendering his decisions or recommendations.

If this attribute—awareness and concern with the affective and secondary consequence of cognitive, scientific decisions and activities—reasonably describes one major characteristic of the ideal physician, a better chance exists for identifying such a person when he or she applies to medical school. There is also a better chance for teaching and practicing such concern after the medical school experience.

The goal of becoming an ideal physician may never be completely attained, but it would seem less courageous to forfeit an unrun race than it would be to lose it after a sincere effort. Without clear recognition of the discernible qualities of the ideal physician and a continuous effort to achieve them, tomorrow's physicians may become little more than tradesmen, unwitting traitors to a great profession and a viable tradition.

Improvement of Parkinsonism in Depressed Patients Treated with ECT

BY ZIGMOND M. LEBENSOHN, M.D., AND RAMON B. JENKINS, M.D.

Two patients with severe Parkinson's disease were treated with electroconvulsive therapy for a supervening depression. Not only did the symptoms of depression clear up after only four treatments, but the parkinsonian signs also showed striking and sustained improvement. This may be related to ECT-induced changes in dopamine and norepinephrine metabolism. Parkinsonism does not appear to be a contraindication to ECT. On the contrary, ECT may be the treatment of choice for certain patients with Parkinson's disease, whether or not it is complicated by intractable depression.

MENTAL DEPRESSION OCCURS commonly in patients with Parkinson's disease. Therapeutic response to tricyclic antidepressant drugs is often disappointing and too slow for emergency use. Many clinicians have been reluctant to use electroconvulsive therapy to treat depression in patients with severe rigidity and bradykinesia. We recently treated two such patients suffering from severe depression and classical Parkinson's disease with ECT. Their depression was alleviated after only four treatments; surprisingly, the objective parkinsonian signs also showed striking and sustained improvement.

CASE REPORTS

Case 1. A 62-year-old lawyer first became ill in December 1961, when he developed an acute paranoid depression precipitated by a stressful situation in his work. He was given six electroconvulsive treatments, recovered temporarily, but later relapsed. In April 1962 he was admitted to a psychiatric hospital where he received perphenazine (Trilafon), benztropine mesylate (Cogentin), and imipramine (Tofranil). His condition remained static, with depression and paranoid delusions predominating. In December 1962 he developed masked facies and decreased arm swing, especially on the right side. Cerebrospinal fluid was normal. The mild parkinsonian signs were attributed to side effects of drugs.

Because his paranoid delusions persisted he was transferred to another hospital and given up to 600 mg of chlorpromazine (Thorazine) daily, 2 mg of benztropine mesylate daily, 10 mg of dextroamphetamine (Dexedrine) each morning, and 5 mg of trifluoperazine (Stelazine) twice daily. He improved rapidly during the next three weeks. The doses of the drugs were gradually reduced, and he was discharged from the hospital on February 5, 1963. He continued to take 2 mg of trifluoperazine twice daily and 200 mg of chlorpromazine at bedtime. These medications were discontinued in March 1963, and he was discharged from treatment without abnormal psychiatric or neurological signs.

For five years he remained well. In January 1968, following a stressful legal case, he again developed delusions of reference, which disappeared when he was given 2 mg of trifluoperazine three times daily for one week, then twice daily for three weeks. However, his parkinsonian symptoms and signs reappeared, and medication was discontinued. Repeated examinations by neurologists over the next several years showed signs of progressive Parkinson's disease, predominantly on the right side. Because of the asymmetry and typical clinical course of the disease, this was considered to be an independent development.

The patient received no phenothiazines for the next four years, but by June 1972 his rigidity and bradykinesia had become much worse despite treatment with trihexyphenidyl (Artane). Within one week he also became depressed, delusional, and pathologically obsessed with trivial episodes from his distant past. Chlorpromazine, in doses of up to 600 mg daily, failed to produce the improvement that had occurred nine years earlier. By June 28 he was so rigid that he could not move, and all medications were discontinued. During the next few months his rigidity and bradykinesia improved slightly, but he was barely able to function. He continued to take anticholinergic agents —benztropine and biperiden (Akineton)—but he was not given L-dopa because of his fragile psychiatric state.

By September 1972 his delusions had returned with such force that he was readmitted to the psychiatric unit of Sibley Memorial Hospital. He was in a state of profound depression and psychomotor retardation. He could not rise from a chair, his face was masklike, and he showed a typical dystonic parkinsonian posture. He had difficulty speaking. He had a shuffling gait without festination. He would recoil when pushed on his sternum but would not fall forward or sideways. There was severe lead-pipe rigidity of his neck and limbs, slight cogwheel rigidity in both arms, and a hint of tremor on the right side. He

Dr. Lebensohn is Chief, Department of Psychiatry, Sibley Memorial Hospital, 5255 Loughboro Rd., N.W., Washington, D.C. 20016. Dr. Jenkins is Chairman, Section of Neurology, Washington Hospital Center, Washington, D.C.

was mentally confused and appeared to have auditory and visual hallucinations. On several occasions he was incontinent of urine.

He was given four ECTs between September 28 and October 5. Each was preceded by intravenously administered sodium methohexital (Brevital) and succinylcholine hydrochloride (Anectine), and they were well tolerated. The treatments were followed by remarkable and rapid improvement not only in his mental condition but also in his physical state. The muscular rigidity and immobility of his face almost disappeared. His speech and gait improved greatly, particularly after the second treatment. His delusions disappeared after the third treatment. He smiled readily and walked about the ward spontaneously. His gait was no longer shuffling, although arm swing was diminished. He lost retropulsion to sternal push. The speed with which he initiated and performed movements was remarkably increased. His superior mental faculties were clearly unimpaired. He was discharged on October 9, 1972.

He has been seen at regular intervals since discharge and has been on a regimen of 2 mg of benztropine mesylate four or five times daily, to which 100 mg of amantadine hydrochloride (Symmetrel) twice daily was later added. Since November 1972 he has resumed his full-time active practice, at which he has remained highly effective. His Parkinson's disease has been stable and there has been no recurrence of psychiatric symptoms.

Case 2. A 70-year-old businessman with a lifelong cyclothymic personality had four severe episodes of manic-depressive illness over a period of 25 years. He had been hospitalized and successfully treated with ECT on several occasions. His last psychiatric illness was a hypomanic episode following a prostatectomy in 1963. This was treated successfully with promazine hydrochloride (Sparine), psychotherapy, and special nursing care. ECT was not used. Promazine therapy was discontinued in January 1964. His recovery was followed by a brief depression, which subsided in April 1964.

He remained well until early 1972, when he developed bradykinesia, cogwheel rigidity, masked facies, shuffling gait, typical parkinsonian tremor, and severe retropulsion. For a while his neurological symptoms were contained by trihexyphenidyl. However, he developed progressive mental depression, primarily because of his inability to engage in many of his previous activities. In February 1973 he became very rigid and immobile. L-dopa (Larodopa) produced remarkable improvement at first, but in spite of increased doses his parkinsonian signs worsened and he became severely depressed. He said, "I see no point in living.... I really want to die." He was unable to sit still and had great difficulty sleeping.

On admission to the psychiatric unit of Sibley Memorial Hospital on April 23, 1973, he was tremulous, anxious, agitated, and despondent. He showed shuffling gait, bradykinesia, and a typical bilateral parkinsonian tremor. He continued to receive L-dopa, the dose of which was gradually increased from 500 mg to 750 mg, four times a day. Meprobamate was given for severe agitation, and he also received 1 mg of benztropine mesylate three times a day.

Between April 24 and April 30 he received a total of four ECTs, each preceded by intravenously administered sodium methohexital and succinylcholine. Immediately after the first ECT the extreme muscular rigidity of his limbs disappeared, only to return an hour later. The next day he showed little or no tremor and he walked without shuffling. He was in better spirits and was able to play bridge for the first time in weeks. After his second treatment he could shave himself and, apart from some slowness in movement, showed no rigidity or any other parkinsonian signs, even though the dose of L-dopa remained unchanged. When he was discharged on May 2, 1973, he was no longer depressed and was walking without difficulty. The improvement in both neurological and psychiatric symptoms has been sustained. The only medication he continues to take is 750 mg of L-dopa four times a day.

DISCUSSION

The coincident improvement of parkinsonian and depressive symptoms in these two patients suggests a common biogenic action of electroconvulsive therapy on both aspects of their illness. The exact mechanism of action of ECT in depressive illness is unknown, but the passage of an electric current through the brain, which produces a convulsive seizure, probably exerts its effects at many anatomical levels and produces many different chemical alterations in the brain, including the concentration and turnover of catecholamines (1–4). The role of depressed levels of brain dopamine in the pathogenesis of Parkinson's disease is now generally accepted. Similarly, the catecholamine theory of endogenous depression has received clinical and experimental support (5, 6). Because ECT improved the parkinsonian signs in these two patients, it is reasonable to ask whether it did so by increasing dopamine synthesis. This would have important implications for the norepinephrine theory of depression. Dopamine is the precursor of norepinephrine, and ECT may produce its antidepressant action by increasing the synthesis of dopamine and norepinephrine.

The therapeutic effectiveness of L-dopa in the treatment of Parkinson's disease is well known (7), but its role in the pathogenesis of affective disorders is less clear. Patients treated with L-dopa have developed a variety of mental changes. These include enhancement of memory, elation, hypersexuality, depression, excitement, hallucinations, delusions, and frank psychosis. The drug may cause deterioration of the mental state of schizophrenic patients (8). Paradoxically, L-dopa has been reported to cause depression (9–11) as well as to alleviate it (12). Tricyclic antidepressant drugs, which probably increase available brain norepinephrine, are effective agents in relieving depression in parkinsonian patients receiving L-dopa. It might be supposed that ECT would act similarly.

Were the extreme rigidity and bradykinesia of our two patients a manifestation of Parkinson's disease or the result of psychomotor retardation? The typical tremor, bradykinesia, severe muscular rigidity, characteristic posture, shuffling gait, retropulsion, and other features of Parkinson's disease clearly confirm that they were in an advanced phase of parkinsonism.
